(5). If crows are noticed in or near the corn field have a boy watch the field for 2 or 3 days, firing a gun now and then when the crows are in sight and showing himself quite openly. Then put up a sort of tent in the field (a stack cover or binder cover will do). The crows are never sure but that the boy with the gun is in the tent and will give the spot a wide berth.

A combination of some or all of the above plans, which are simple and inexpensive and have been tested out with good results, will soon persuade the crow that teh locality is an undesirable one.

Cost of Mutton Production

(Experimental Farms Note)

The scarcity of wool and meat has given a new impetus to the sheep breeding industry in Canada and once it becomes firmly established as a common farm industry and the benefits coming from it are fully recognized, the writer feels confident that it will not again go into decline.

This class of stock, while enjoying to the full the benefit of the increased high prices of the products produced, is probably the one which has been affected the least by increased cost of production, common to the products from other closses of stock. This is due to the fact that the feed consumed consists larely of home grown roughages and grains thus eliminating, to a large extent, the purchase of high priced consentrates. It is also due, in part, to the fact that very little labour is required to handle a flock so that the increased price of labour has not the same effect.

To arrive at the cost of mutton production many factors must be taken into consideration. It may be safely considered that the value accruing from the manure produced and weeds destroyed fully offsets the labour expended. From the records of the breeding and feeding work at the Central Experimental Farm, the remaining factors in the cost of production of year old mutton may be tabulated as follows:—

Cost of feeding maintaining ewe from weaning of one lamb to weaning of next	$5.00	
Interest on value of ewe ($3.00 at 6%)		1.80
Service charges and maintenance of ram		.35
Cost of feeding lamb from weaning till finishing at one year old	6.72	
		$13.87
Wool from ewe (7 pounds at 60c per lb.)		4.20
Cost of 120 pounds mutton		9.67
Value of 100 pounds mutton, Spring 1918		17.75
Cost of 100 pounds mutton		8.06
Profit per 100 pounds		$ 9.69

This is a profit of $11.63 per lamb if but one lamb is raised per ewe.

The above figures are based on an increase of one lamb per ewe. Where two lambs wre raised practically the same results in weight may be expected at the end of the year. In such a case the first three items in the cost would be split between the two thus reducing the cost of $5.09 per hundredweight and increasing the profit to $12.66 per hundredweight.

The foregoing estimates are exclusive of overhead charges or depreciation but these items may well be overlooked as they are almost negligible in sheep raising owing to the fact that so little is required in buildings or equipment. Moreover the estimates are conservative and though they show a return of at least 38.8% on the investment of $30.00 per ewe, the same may be looked for under Eastern conditions while under Western conditions even greater dividends may be realized.

Raspberry Leaf Curl

(Experimental Farms Note)

In the interests of market gardeners and small fruit cultivators, this note on Raspberry Leaf Curl has been prepared at the Field Laboratory in Southern Ontario at St. Catharines, and is issued by the Central Experimental Farm, Ottawa.

This disease has been known for some time both under the above name, as well as under the name of Raspberry Yellows. Since the curling of the leaves is the most outstanding feature in connection with the disease, it is preferable to use the term Raspberry Leaf Curl.

The disease affects the leaves and shoots and is often confined to a single bush or part of a bush, some of the shoots being perfectly normal and others with the leaves affected. The affected shoots, instead of producing normal large, broad leaves, bear leaves which are conspicuously small and badly curled downwards. In the early stages this sympton is not so pronounced, and while a small amount of curling may occur then, the diseases is more noticeable on account of the yellowing which takes place during the summer because of the unhealthy state of the foliage. Since yellowing of the leaves may be due to a number of other causes, such as wet feet, poor soil, drought, etc., it is best to determine the disease mainly by the Leaf Curl symptons.

In the advanced stages, the canes bear no fruit. When first attacked, they flower almost normally, but the fruit is small and dry and shrivels up before ripening, so that little or no fruit is ever produced from an infected bush. Of the three varieties which are commonly grown in the Niagara district, Cuthbert, Marlborough and Herbert, the Herbert seems to be freest from the disease. The other two varieties are quite susceptible, but one rarely sees signs of Leaf Curl in the Herbert.

So far as is known the disease is not due to any parasitic organism. It apparently belongs to that type of trouble which has been called physiological disease, and could therefore be put into the same class with peach yellows and little peach, and the mosaic diseases of tomatoes, tobacco, potatoes and so forth. No records are available as to how the disease is brought into the field in the first place, nor how it is transmitted from one plant to another. It undoubtedly does spread once it becomes established in a plantation and many fine plantations are known to have been greatly injured by the presence of a large number of Leaf Curl plants. If the disease corresponds closely with the mosaic or yellow disease, one would suspect that it is carried either by insects or pruning operations.

Although too little is known about Leaf Curl to advise a sure means of control, one should always remove the affected plants as soon as they show signs of disease. They are of no use in any case and are likely to spread the disease to other parts of the plantation. In taking out Leaf Curl plants, one should be careful to get the whole of root system, otherwise the parts that are left will start to grow and produce new shoots which will also show Leaf Curl. It is possible that some of our Leaf Curl originates from nursery cuttings and some care should be taken when setting out a new plantation, to avoid this disease.

THE MARITIME FARMER.

And Co-operative Dairyman
Registered Trade Mark

Semi-Montbly Journal devoted to the interests of the farmers of the Maritime Provinces.

Official Organ of The Farmers and Dairymen's Association of New Brunswick; The Nova Scotia Farmer's Association; The Nova Scotia and P. E. I. Fruit Growers' Associations; The New Brunswick Fruit Growers' Association; The Maritime Stock Breeders' Association; The Maritime Bee-Keepers' Association; The New Brunswick Poultry Association, and the Newfoundland Agricultural Board.

Subscription price $1.00 per year. This paper is sent to subscribers unless a definate order for discontinuance is given.

The date after your name on the little green label on front page, is in every case the time to which your subscription is paid.

OUR GUARANTEE.—With each subscriber to the MARITIME FARMER, we positively guarantee, while bis subscription lasts, that no advertisement is allowed in our columns unless we believe that any subscriber can safely do business with the advertiser, and we agree to make good any loss which any such subscriber may sustain by trusting any such advertiser who may prove to be a deliberate swindler; but we do not undertake to adjust trifling differences between subscribers and responsibl advertisers. To take advantage of this guarantee, written come plaint must be made to the publisher within one week from the date of any unsatisfactory transaction, with proof of the swindle and loss, and within one month from the date when the advertisement appeared, and the subscriber must prove tbat in writing to the advertiser he said:—"I saw" your adv. in tbe MARITIME FARMER.

SCREENINGS

Screenings are all wrong for seed, but all right for feed. A common argument of those who sow grain just as it comes from the bin is that the worthless stuff in it might just as well be wasted in the field as to be thrown out behinds the barn. It is not the waste but the pest of weeds which is of most importance in most cases of screening. Along with the weed seed should be classed the small, shrunken or light kernels. The grain cleaner is one of the most profietable pieces of farm machinery. It has been demonstrated over and over again that plump, heavy seed gives larger yields than light stuff. Screening reduces the percentage of weeds in the crop. While screenings are worse thon worthless when sown in the field, they are worth just about full value when fed.

Two students at North Dakota Agricultural College fed one pen of sheep ten weeks on oats and bran, one pen on the seeds of a weed known as pigeon grass and a third pen on screenings. Those getting oats and bran made the smallest gain. The sheep to which pigeon grass was fed gained 16 pounds more and ate only 12 pounds more of the feed while the lot receiving screenings gained 34 pounds more than the oats lot and ate just 12 pounds more screenings than the first lot ate of oats. Screenings commonly amount to 2 or 3 pounds per bushel of wheat and twice as much of oats. Indeed, some oat growers are so particular that they screen out fully one-half or more of the oats in order to get a high grade of plump heavy seed. We hope you put the screenings into the feedbox instead of the seedbox this spring.

GETTING AT THE BOTTOM OF THINGS

Observe the different manners in which two men will poke a grate fire. One will content himself with hammering at the coal on the top of the fire, making a little smoke and possibly hastening the combustion a little. Another, a little more thoughtful and patient, will take the poker and stir down under the grate until he gets the ashes out from beneath the coal, letting the air up through the mass. Then without more fuel or attention it flames into a ruddy glow; the fire is a success.

Now that is like the dicerent methods of meeting the farm's problems. One man whose farm is more or less a failure hammers away in the old way at the things nearest in sight, working as hard as he can, and keeping his boys at it as hard as they can go it, plowinig the same field over and over without drainage or fertilization, keeping the same old cow, without testing The fire they get is feeble and insufficient. The profit of their farm is probably in the minus column. The other man, who would have poked the fire from beneath to let the air in, findinig his farm unprofitable or unsatisfactory, uses thought and reason. He discovers the farm's need of drainage, he attacks that. He finds the need of phosphorous and supplies it. He see the lack of legumes on the ground; he sows them. He sees the need of better animals; he gets the better cows and testing them, keeps only those that show a profit. Probably he may not work as hard as his neighbor across the fence but when he has let the air into the soil by the good drainage and has the phosphorus, the legumes and the good animals on the farm then everything comes up fienely of itself, and the very best things seem to happen as though by magic. It was not accident at all. It was planning; finding the source of troubles and curing them. It was letting the air in under the grate. It is what we call well-directed energy that goes to the bottom of the trouble, whether it is a grate fire or a sour and unproductive farm.

LEADERS IN RURAL COMMUNITIES

Make the farm as profitable as we may, we cannot realize returns sufficient to hold there the ambitious boy whose aim is to accumulate vast riches. True, there may be exceptions to this rule, but it applies in a very large percentage of cases. The country makes in the main, neither millionaires nor mendicants, but it is a great place for the development of men. It is in cities that the financial gulf is wide. There we find wealth and want. There is the chance to become a millionaire—yes, and the danger of becoming a mere cog in a machine. Yet, unafraid, the fortune-seeker leaves the farm.

Not every country born boy should remain in the country. The city needs many of these lads fresh from the life-giving, brain-and-brawn-building land, but for the country's good—and the nation's, too—the drain has been too heavy.

The most lametable lack of country life is leadership. So it is of prime importance that a fair proportion of the youth who may become leaders remain in rural communities. How is this desirable end to be brought about? Largely by holding up to the ambitious farm boy the right kind of ideals and getting in his mind the best ideas, by giving to him a vision filled with the porper attitude toward work and the world, by making it possible for him to see in farm work more than dirt and drudgery. The worker must see in his daily duties tasks worthy of his talents. Herein lies the strength of our schools and of teaching and research work in agriculture. Science is valuable not alone for the limited mastery it has given to man over the soil, growing plants and animal life with which he daily comes in contact, but it serves also to enable him to see in these thnigs interest, possibilities, power and a field for unlimited research.

So with farming made sufficiently remunerative as to give to its followers reasonable returns with interest quickened and success properly defined, we may, without the possibility of great riches for the many, see fewer country born boys turn to the city.

LOAFING

We now have an anti-loafing law. Said law was not enacted too son. May it long continue in force after the crisis which has brought it into being is all over and pushed into the dim and distant past.

—All the loss from loafers is not occasioned by the idlers who frequent street corners or sit about the stoves in small-town stores. There is loafing on the farm and, strange, as it may at first seem, many a hard-working farmer is a heavy loser from loafing. He may not loaf, but he may allow a part of his farm to loaf; or it may be his cows or even his chickens. The brush-grown lands which if cleared would grow good crops of cereals or oats, is land that loafs. The same is true of the lowland that needs draining, or of the land that is taken up with a crooked stream that could be straightened. And in the cultivated field, where untested seed is planted and a poor stand results, there is land that loafs. Here, too, is labor that is lost. The cow that fails to pay her board bill is a loafer; so are the surplus work horses that seldom work. Land values and interest rates are too high to allow of any unnecessary loafing on the farm. Every acre and every animal must do its duty.

AS TO NAMES

There is something in names. This is the age of travel by auto and because it is there is an added need of names. Where formerly one stranger passed by a farm on a well kept road there now journey a hundred strangers. So the value and pleasure possible in a farm name are increased manyfold. There comes too, a real demand for named roads and for signboards. And why not, on the main traveled street in each town or village, the name of the place so that he who rides can read? Would it not be an effective bit of advertising for any town or county to have all its main roads and the farms along them named and the names prominently displayed, signboards at road turns and crossings and town and hamlet names in plain sight?

"Nameless" is not the word that we associate with joy and success. "A good name" has a scriptural sanction.

* * *

A Southerner greatly interested in the encouraging of home industry and a strong advocate of the principal of producing as many commodities a thome as possible, delivered the following address to a group of farmers:

"Now, my farming friends, what the matter with you is that you don't live at home, you haven't practiced and learned the fruits of conserving and utilizing your own resources. The great trouble is that you have contented yourselves with continually buying something from somebody else and selling nothing to anybody. Now to ilustrate what I am talking about, I want to call your attention to the fact that when you awake in the morning it is to the alarm of a Connecticut clock. You get up and button your Chicago suspenders on to your Detroit overalls; you go out and wash your face in the morning in a Toledo wash pan with Cincinnati soap. You sit down to the table and eat breakfast from a table made in Grand Rapids, Michigan. And for your breakfast you eat Chicago

meat, Tenesee flour cooked on a St. Louis stove. You go out and put a New York bridle on a Kentucky mule fed on Iowa corn. And all day you plow a farm covered with a Massachusetts mortgage, with a plow made in Chattanooge, Tenessee. And when your day's work is over and you go home at night you read a bible printed in Boston. You read a prayer written in Jerusalem and you crawl under a blanket manufactured in the State of New Jersey to be kept awake all night by a damn dog, the only home product on the farm."

The foregoing pretty nearly expresses the feed situation in the Maritime Provinces. Can it not to a certain extent be remedied?

CLOVERS AND CLOVER SEED PRODUCTION

(Continued from page 547)

are not so troublesome and, as the second crop does not usually grow so high, the weeds can be seen and removed. It will pay to do it. The cleaner the seed, the higher it will grade; and the higher it will grade, the higher price that can be obtained for that which is to be sold.

Time to Cut for Seed.—As a rule, the second crop may be cut for seed when nearly all of the heads are well browned. Do not be governed altogether, though, by the number of browned heads. It is well to go carefully over the field and pluck a few heads here and there and rub them out in the palm of the hand. If the heads shell easily and the seeds come out clean, it is time to cut. If the seed is soft and not properly filled, or if it cannot be shelled out easily, let the crop stand, even if a few of the riper heads are lost. If the seed is ripe in the head, the earl yfrosts of fall will not hurt it. If the seed is not ripe, it will not be good for sowing, even if cut to avoid frost. A common mistake made my inexperienced clover seed growers is to cut the seed crop too early.

How to Cut.—The old self-rake reaper was commonly used in Western Ontario for cutting seed and a few may be found on farms to-day, kept for this purpose. Some implement companies manufacture a clover harvester which is especially designed to cut clover seed. Any farmer who has not one of the self-rake reapers, or a clover harvester need not be deterred from growing clover on this account as other devices can be used. The ordinary mower can be utilized for this purpose. It should be used in the morning while the dew is still on, to prevent the seed from shelling. A better arrangement is the ordinary mower with a table attached to the cutter bar. It requires two men to handle this outfit. A couple of holes are drilled at the back of the cutter bar and the table is attached by means of wire close up to the cutter bar and allowed to drag on the ground behind. A man follows with a fork or rake to keep the clover drawn back on to the table, and pushes it off to one side in windrows. The ordinary grain binder may also be used, the twine and the trip arm may be removed and the two small boards that hold the sheaf may be slackened or removed in order to allow the clover a free course to the ground. This will lay it out in a swath on the stubble in a splendid position to dry and out of the way of the horses and machine. If the clover is high enough to permit of cutting in this way, it is probably one of the best methods which can be used. The windrow can be easily gathered with a barley fork.

The length of time to allow the clover to remain in the windrow will depend on the weather and the condition of the crop when cut. It frequently happens that the crop will have to remain out two or three weeks before it is dry enough to thresh or draw into the barn.

Method of Threshing.—The clover huller is the best machine for threshing the seed. A better job can be done with this machine than with any other, but it is not absolutely necessary to have a huller. A fairly good job can be done with the ordinary grain thresher providing certain adjustments are made. If the clover straw is to be used for feed, it might be well to run the material through, just the same as grain is put through. This will separate the heads and chaff from the straw. The heads and chaff can then be put through a second, or third time, but before putting them through, a plate of sheet iron or a hard board should be placed directly behind the cylinder, closing up all of the back space except about nine inches on the left-hand end of the cylinder. Another board should be placed in front of the cylinder to close up all except one foot at the right-hand end. All small holes in the concaves should be closed and the concaves set as close to the cylinder teeth as possible. This will cause all of the material to pass from one end of the cylinder to the other, which will hull the seed much better than if passed through in the ordinary way. The chaff can be put through two or three times carefully, and it will be found that nearly all of the seed will come out clean. This is not as good as the clover huller, but is very useful when a huller cannot be obtained.

Alfalfa Growing.—Alfalfa has been tried on many farms in Dundas county with varying degrees of success. Those who have not succeeded in growing it have likely either used seed not suited to the climate, or have not given the crop the attention which it demands. Only the hardiest strains will survive our cold winters. The genuine Grimm and the Ontario Variegated have given successful results on farms where the less hardy strains have failed to survive. Where common red clover grows well and gives good results, there is not so much need for trying to grow other clover crops. However, those wishing to try alfalfa should sow only seed of hardy strains, such as those above mentioned. Alfalfa seed can be successfully grown on Dundas County farms. Those wishing to grow alfalfa will secure better results if they have a small plot and grow their own seed. A pound or two sown in drills, say 30 inches apart, and cultivated two or three times in the spring, will yield a sufficient quantity of seed for the ordinary farm. The seed should be taken from the first crop, as it has been found that the second crop of alfalfa in Dundas county does not produce seed successfully, or in sufficient quantity to warrant cutting the first crop for hay and keeping the second crop for seed. Three pounds sown in drill should sow at least one acre. A little alfalfa sown with the regular clover might be a factor in bringing about earlier cutting of the general hay crop. This is already practised by a number of farmers, who state that they have had good success with a mixture of alfalfa and common red clover and timothy. Alfalfa, however, should under ordinary conditions, be cut a little earlier than the common red clover.

THE SILO AN ECONOMIC NECESSITY

The cheapest and best ration for live stock must contain a reasonable amount of succulent feed. An abundance of suitable pasture is unexcelled, and a substitute for this feed in winter or during a drought in summer is essential for greatest production and profits.

In view of the scarcity and high prices of grains and meals, the silo takes on an increased value. For example:—100 pounds total digestible nutrients in corn silage has a net cost of 54c, in bran $2.31, corn $4.02, oats $4.29, etc., when silage costs $3.00 per ton to raise and store and other feeds are valued at present wholesale market prices. Even in these times of expensive labour, seed, horse labour and machinery, corn may be placed in the silo at the above cost. Surely this is sufficient reason why every live stock farmer should consider the increase in silage production.

The adaptability of the silo to various parts of Canada depends on the location, varieties of crops which may be grown, and, to a lesser extent, on the class of live stock maintained. No farmer with two or three cows should think of building a silo, but for a herd containing ten cows or more, or the equivalent, a silo may advantageously be erected. Silage is feed pre-eminently suited to th feeding of dairy cattle. It, however, is a very excellent and cheap feed for beef cattle, sheep and horses. In the majority of the best live stock districts in Ontario and Western Quebec silos should be on every stock farm. In the Maritime Provinces, Eastern Quebec and British Columbia, all large stock farms, particularly of dairy cattle, can use a silo to excellent advantage. If any particular district is not suited to corn growin, peas and oats, peas, oats and vetches, clover, alfalfa, etc., may be substituted for that crop. In the Maritime Provinces, silos on many farms, particularly on large stock farms, are operated satisfactorily.

Silos for Winter Use:—Silage at $3.50 per ton is cheaper cattle feed than mixed hay at $12 per ton. Corn silage is 30% better than shocked corn from field. The same holds equally true of unthreshed oats or oats and peas saved for winter feed. Silage from peas and oats produced milk 20% cheaper than oat sheaves, 30% cheaper than straw and turnips and 40% cheaper than hay. At the same cost per ton, silage is better feed than roots for beef or dairy cattle. Moreover, considering present labour condi tions as well as cost of harvesting, keeping qualities and cost of storage, silage, where grown successfully, is more economical than roots. Silage needs no pulping or other preparation for feeding. Silage for winter use is in itself the cheapest feed, and it also makes all other roughages and grains more palatable, wholesome and profitable.

Silos for Summer Use:—Good pasture, if available, is the cheapest summer feed. Where permanent pastures fail, an annually sown pasture of rye or oats and barley may, under present labour conditions, be the cheapest substitute. However, the use of soiling crops or summer silage may be the only available means of providing succulents. As a rule, silage is more profitable and more cheaply grown than are soiling crops and is more cheaply harvested and fed during the busy season. Milk produced on corn silage and green cut alfalfa cost in feed 66c per cwt.; produced on corn silage and mixed hay may cost 70c per cwt.; produced on soiling crop (peas and oats) cost $1.04 per cwt. With all lots, the heavy milkers received some grain. Where suitable pastures are not available the summer silo provides the cheapest feed and greatest profits.

Finally, the farmer with a silo need never fear losing a crop of clover, alfalfa or late-sown grain. Silage making does not depend on the dryness of the weather. The silo is the cheapest storage building on the farm in proportion to the tonnage capacity. The silo allows the carrying of more stock per acre on the farm and is a labour saver, a money maker and a soil enricher.

This is the season of the year to build more and better silos.

HOW TO KNOW WHAT TO USE

"How shall the farmer know what analysis of fertilizer to use on his crops? It is a case of feeding the crops the same as you feed your live stock. It is common knowledge that sandy soils are relatively short in ammonia, phsphoric acid and potash. Clay soils that have been under crops for some time are usually short of ammonia, fairly well supplied with phosphoric acid and potash, but the phosphoric acid is usually in a slowly available form. Much soils are relatively well supplied with ammonia, but in rather unavailable form—weak in phosphoric acid and very weak in potash.

"Growing crops themselves on soil in good condition are pretty clear indicators of the plant food needed. For instance:

"If the straw or stalk of grain or corn is short and poor there is pretty clear indication of the need of more ammonia or nitrogen.

"If the crops fail to ripen within the growing season, and the grain fills poorly, there is indication of lack of available phosphoric acid.

"If the straw is weak and the grain is easily attacked by disease, and if the potatoes are small and the kernels of wheat, oats and barley are poorly filled, there is indication of a lack of potash.

"Now, if the farmer has in mind the natural crop indications and general knowledge of the characteristics of his soil types, he can determine with a fair degree of accuracy what analysis of fertilizers will be likely to give profit on crops he intends to grow."—Henry G. Bell.

GOVERNMENT NOTICE

CANADA FOOD BOARD.
16th March, 1918.

Order No. 24.

Whereas by order of the Governor General in Council, dated the twelfth day of March, 1918, P.C. 597, it was amongst other things provided that the Canada Food Board shall have power from time to time to order that any food or food products held by any wholesale or retail dealer or by any warehouseman named in such order, shall be forthwith sold in such manner as the Canada Food Board may direct,

And whereas it is advisable to prevent, as far as possible, eggs from spoiling and to prevent the sale of spoiled eggs.

Therefore, the Canada Food Board doth order, that:—

1. No person operating any cold storage plant shall receive eggs for storage or shall store eggs therein without an accompanying certificate in writing from the owner of such eggs, certifying that said eggs have been candled and all bad and unsound eggs removed.

2. No person dealing wholesale in eggs shall receive or demand payment for bad eggs in excess of a margin of allowance of one per cent on the total of each transaction.

3. This Order shall take effect on and after the sixteenth day of March, 1918.

Dated at Ottawa, this sixteenth day of March, 1918.

Canada Food Board,
HENRY B. THOMSON,
Chairman.

THUNDER STORMS WON'T SOUR MILK THAT IS PROPERLY CARED FOR

There is a wide spread belief that thunder sours milk, for testimony is not lacking that after a severe electrical storm, milk that should have been sweet is found to have soured. It is quite natural that the souring should be attributed to the thunder but we shall need to look elsewhere for the cause of the phenomenon. Souring is caused normally by the acidity which results from bacterial growth and sterilized milk will not sour in a thunder storm. Neither will milk that is kept on ice sour during a thunder storm. The probable explanation lies in the fact that during storms of this kind the temperature is raised sufficiently to favor the multiplication of milk-souring bacteria where the temperature is not regulated by the use of ice.—W. H. Feldman.

If possible, medicine for sick fowls should be administered in the food or drinking water. Catching a hen and forcing medicine down her throat throws her into such a nervous state that the excitement often does more harm than the medicine does good.

HORTICULTURE

THE SECOND SPRAY FOR NOVA SCOTIA APPLE ORCHARDS 1918

A number of different formulas have been used in this spray and as there is somewhat more danger of injury at this time than in the previous spray, more care must be exercised in the way the spraying is done.

Regular Formula.—Lime sulphur, commercial concentrates 2 1/3 gals. to 100 gals. of water with arsenate of life 2 lbs. to 100 gals. is used at this time. In spraying with this combination, care should be taken to direct the spray at the upper surface of the leaves, or some injury may result, particularly under certain weather conditions and in some locations.

Substitutes.—Bordeaux mixture according to the Thompson formula (2-10-40) is preferred by many for this spray on acount of its safety. This material has been used by a number of growers for two or more years and has resulted in a good crop of clean apples. It has bee found to be perfectly safe to use on foilage at this time, causing no burning or dropping of the fruit. The fruit may not be of such bright color as when other sprays are used and there may be e very sligth amount of russetting, chiefly of the "netting" type. The foilage on trees sprayed with this combination has invariably been excelent even when used four times in sucession. without the yelowing or bronzing of the leaves that is likely to follow the repeated use of the 4-4-40 Bordeaux. The 4-4-40 Bordeaux used at this time will give good control of scab, but may result in from 10 to 60 per cent. of slight russetting, together witha bronzing of the leaves, especially if preceded by a similar spray.

Arsenate of lime ¾ lb. or arsenate of lead 2 lbs. to every 40 galons of spray may be uesd, the chief consideration beig one of cost, since both are perfectly safe to use with this combination.

Modification for a Bad Outbreak of Canker Worm

If a very bad outbreak of canker worm is anticipated the most satisfactory spray is arsenate of lead 10 to 15 lbs. to 100 gals. of water. In the interests of safety it is better not to employ a fungicide at all when this is necessary, particularly as arsenate of lead in this strength has considerable fungicidal value.

Modificatoin for Green Apple Bug

In spraying for green apple bug, it is necessary to use a very heavy drenching, driving spray covering the under as well as the upper surface of the leaves, applied at a very high pressure. Most sprays aplied in this manner will cause no injury but the safest combination we have tested to date consists of soluble sulphur 2 lbs., blackleaf 40, ¾ pint to 1 pint, water 100 gals. To this we have added a soft fish oil soap at the rate of 4 lbs. to 100 gals. This causes the liquid to spread better and helps to liberate the nicotine. If the soap cannot be obtained, hard soap shaved fine dissolved in water, will do, but this takes time and some kinds cause burning. Probably soap powder poured right into the tank would do the work but we have not tried it as yet. **No poison should be added to this mixture or burning will result.** If the orchard was given a thorough spraying with poison in the preceding aplicationi it will not always be necessary in this one, as the foregoing mixture kills many biting insects by contact.

If absolutely necessary to use a poison, or if another bug spray is to be given, use lime sulphur instead of soluble sulphur and leave out the soap. Reduce the strength of the poison, however, as this mixture is more likely to cause injury. This is the most important spray for the bug and unless well done is worse than wasted. To attain success begin to spray just as late as possible before the Gravensteins open, use twice as much material and twice as much time as in ordinary spray and spray each limb from every angle. Use as much pressure as you can obtain even at the risk of some mechanical injury. Unless it is intended to follow all th eforegoing faithfully, it is far better and will save money not to make the attempt. Even where the green apple bug is not present a spray of soluble sulphur has been employed with success by growers as a regular spray. The folowing formula may be used:

Soluble sulphur	3 lbs.
Arsenate of lime	1½ lbs.
Lime	25 lbs.
Water	100 gals.

Application

In using lime sulphur direct the spray at the upper and not the under side of the leaves, standing well off from the trees or on top of the cab so a snot to cause mechanical injury with the strong stream from the spray gun. In spraying for green apple bug about twice as much material will be required as is ordinarily applide and as much pressure as can be obtained.

Pests Destroyed

In ordinary years this is the most important spray and should never be omitted. If the first spray has not been given it should be applied a few days before the blosom buds are showing pink at the top. This is the time that apple scab usually begins to show and especial care should be exercised in its application to prevent this disease getting a foothold on leaves and blossoms stems and causing a beavy drop of the fruit. Bud moths, fruitworms, canker worms, tent saterpillars and brown-tail moths are among the biting insects destroyed and the residue tfrom this spray is of service in the control of the codling moth in Nova Scotia. In many places this season the canker worm will be the most important pest to control at this time, and arsenate of lead as recommended is the best method to employ.

Notes on Second Spray

Do not use Arsenate of Lime alone.

Do not add soap to a combination containing Lime Sulphur.

If a weaker dilution of lime sulphur is used than that recommended either the quantity of Arsenate of Lime added must be correspondingly decreased or else lime must be added to prevent leaf yellowing.

Five pounds of stone or hydrated lime added to the straight lead arsenate, 10 to 15 lbs. to 100 gals., will prevent yellowing of foilage.

Do not omit the stone or hydrated lime from the soluble sulphur arsenate of lime combination.

Do not allow Soluble Sulphur to stand exposed to the air, keep in a closed container.—G. E. Sanders, Dominion Entomological Laboratory, Annapolis Royal, N. S.

PRUNING AND SPRAYING A NEW YORK ORCHARD

(From American Agriculturist.)

As soon as practicable after our fruit is picked we begni pruning. Our object is to have low-headed trees, open as much as possible to admit light and sun and as nearly symmetrical as we can make them. In heading back our trees we begin with the central branches, cutting out enough wood to bring our tops about 24 feet from the ground. . We then graduate down on the sides of the tree.

When finished there is just enough variation between the branches to give perfect balance and form. Often will be found in old apple trees many vacant spaces 6 or 8 feet in size without any branches. These spaces can be filed in the second and third year after heading back the trees by pruning back the water sprouts which break out al over the branches which have been severely pruned.

I cut these sprouts back to about 4 inches, leaving my last cut on the outside of cut, so as to throw my new branch out ward from the tree centre. The following summer when thesething which we have no use for in our sprouts have made about 8 inches oforchard. My object of removing this growth. I pinch back the ends so asscale bark is to give a better chance to start new lateral branches to helpof combating the various forms of balance my future limb, also checkingscale insects that find a safe harbor the growth, which will casue fruitunder the loose bark, where the spray-space to appear, after which the newing material can touch them. growth will not be so rapid. We now spray our trees, which I

Be Sure of Your Weight

Be certain the goods you buy and sell are correct weight. Mistakes are always possible but accurate weight is assured by

Fairbanks Union Scales

They save their cost every year by eliminating short weights in buying and overweights in selling. They are the most convenient size scales for general light weighing anywhere.

They replace the old time spring balance scales condemned by the Canadian Government.

Complete with tin scoop, 10½" x 13½" platform, single brass beam and extra weights. The scoop capacity of Fairbanks Union Scales is 30 pounds by half ounces — the platform, 240 pounds by quarter pounds.

They are strong, compact, simple and guaranteed absolutely accurate.

Write our nearest branch for information and prices of scales for any weighing purpose.

GROW STRAWBERRIES

In the rush of other work, do not forget to set that new bed of strawberries this spring. Many growers are cutting down their acreage on account of labor difficulties and the high price of other crops. Production for the next few years will be cut in two and berry prices are sure to be high. Our advice to our fellow Fruit Growers is, grow all the grain you can, but DON'T GIVE UP THE STRAWBERRY. Among other varieties we recommend Senator Dunlap and Warfield at $4.00; Sample, Arnout, Buster and Glen Mary at $5.00; Wm. Belt, Dr. Burrell, and Bubach at $6.00 a thousand. The great everbearer, Progressive at $1.25 a hundred. Send a card for our free Catalogue.

CYRUS & MANNING ELLS, Port Williams, N. S.

A Sterling Government Investment

You help yourself, your family and your country when you buy Victory Bonds.
Yourself, because they provide the safest and most convenient form of investment—with an interest return better than many speculative investments.
You help your family in the event of your demise, as the investment is easily looked after and contains absolute assurance of prompt and continuous payment on interest dates, and prompt repayment of principal at maturity.
Or the Bonds may be borrowed upon or sold any moment if money is urgently needed.
You help your country by providing the sinews of war.
If you have money for which you have no immediate use that is not drawing interest or drawing only 3% interest invest it in Victory Bonds.
AND REMEMBER VICTORY BONDS ARE FREE OF FEDERAL TAXATION.

A $50 Bond costs.....$ 49.45
A $100 Bond costs..... 98.87
A $500 Bond costs..... 494.37
A $1,000 Bond costs..... 988.75

and accrued interest in each case. Larger amounts in proportion. Interest payable every six months at all banks without charge.
Upon receipt of your application we will send bonds to your local bank, where you may inspect them before purchase, and you may pay us for them through your local bank without extra charge or exchange on cheque. Address Dept. F.

the material, which is bound to run downward. Our apparatus consists of a 100-gallon tanak, mounted on a cut-under 4-wheel wagon. We have an elevated platform, 8 feet high on the truck. The driver is stationed up there with a 10-foot spray rod, and ca ncatch the tops of the trees on both rows.

On the ground I have two men, each with a 10-foot rod and 60 feet of one-half inch hose, which gives them a chance to work half-way around the trees by the time the driver has sprayed the tops. We make two sprayings, wintetr or early spring, with scalecide, and at the second spraying we use bordeaux and arsenate of lead, as the blossoms begin to fall. By using the above mixture we control both fungus and insects with one spraying.

Cultivating the Orchard

We have now pruned and sprayed the tree. Plowing comes next. We plow, cutting about 4 inches deep near the trees and 6 inches as you work away from them, being careful not to cut any large roots. After the plow we use the cutaway harrow and pulverize the sod. Use your spike-tooth harrow and level the soil. To seed aliske clover, brush it in and roll the earth down firm.

Watch the clover grow, and when in bloom cut and let it lie as you cut it. If your soil has any life in it at all, you will have a second stand. In my orchard I leave this second crop to seed, then cut it down and leave as cut These two cuttings will give you a good mulch all over your orchard I repeat the above every three years, and find my trees appreciate it by giving me a crop of apples year after year, also a good crop of leaves which help enrich the soil.

TREES INJURED BY MICE OR RABBITS CAN BE HEALED

If a tree is badly girdled by mice or rabbits it usually dies if left untreated. If, as soon as the wound is noticed, it is cleaned and covered with grafting wax or some paste, such as sulphur, cowdung and clay, and wrapped with a cloth to exclude air and prevent the wood from drying out, there is a posibility of saving the tree if the girdle is a small one, as the sap which rises through the wood will continue to do so, an dreturning through the inner bark in na elaborated condition will cause growth to be made all around the upper part of the wound and if the latter be not too large there is a chance of its healing over. If, however, the wood becomes dry before the bandage iis put on, the tree will almost certainly die, although it may continue to grow throughout the season. When the wax and bandage are applied the tree should be headed back considerably to lessen the amount of transpiration of moisture as there will not be as much sap rise as if the tree were uninjured and the wood will thus dry out sooner than if it were headed back. If the girdle is near the ground in addition to covering the injured part with wax or cowdung and clay it is advisable to mound up the soil about the tree to cover the wound and thus help to prevent the wood from drying out. The mound should be up about six inches above the wound and be about two feet across at the base.

At the Experimental Farm girdled trees are frequently saved and more surely saved than by the above method by connecting the upper and lower edges of the girdle with scions which are inserted about an inch apart all around the trunk This is known as bridge grafting. The more scions that are used the more quickly they will grow together and form a new trunk, but two or three scions successfully grafted on a small tree will carry enough sap to keep the tree alive. A slanting cut is made at each end of the wound in the uninjured wood in which the ends of the scions are to be inserted Strong, plump scions of the previous season's growth—not necessarily from the same tree, nor even the same variety—cut a little longer than the distance between the slanting cuts, are made wedge-shaped at each end. They are made a little longer than the distance between the cuts in order that when inserting the ends into the cuts it will be necessary to bend them, and thus have them under pressure, which helps to keep them in position After inserting, some of the inside bark of the stock should remain in contact with the inside bark of the scion, as it is here, or at the cambium layer, where union takes place As soon as the scions are all placed, the wound, especially about the ends of the scions where inserted in the stock, is covered with grafting wax. The ends are also at th esame time bandaged with a piece of sacking around th etrunk to aid in keping the scions in place and to exclude the air. The tree sould be well headed back. The scions, if properly made and in-

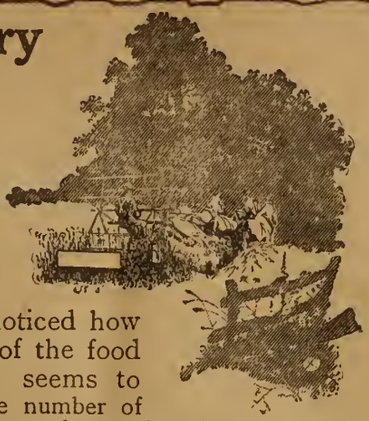
No Worry About Harvest



HAVE you noticed how discussion of the food supply situation seems to center around the number of acres it is possible to plant rather than around the harvesting of those planted acres?

It is an unconscious, but none the less wonderful, tribute to the genius of the inventors of the reaper and binder that the public takes the harvesting of the greatest grain crop ever planted as a matter of course. The sole question now is, "How many acres can we plant?" The power and help required by the planting will be amply sufficient for the harvest where **Deering** binders and binder twine are used.

And, where they are used, the harvest will be complete. No matter whether the grain be tall or short, heavy or light, standing or down, lodged and tangled, a **Deering** binder cuts and binds it all without waste.

It is an easy matter to be fully prepared for harvest. Buy the largest binder you can use. The larger sizes conserve labor. Buy a new machine if there is any question about the efficiency of the old one. A new **Deering** is absolutely reliable.

We furnish promptly either new **Deering** binders or repairs for old ones. Do not hesitate to call on our organization for any help we can give in the harvesting of this year's grain crop—the most important crop ever raised. See the local dealer or write to the nearest branch direct—early.

RAISING CROPS ON RAILWAY PROPERTY

Canadian Government Railways Urging Employees to Cultivate on Right of Way.

Employees of the Canadian Government Railways located conveniently near sections of the "Right of Way" where the soil is suitable for cultivation, are being urged to apply for such land as they can cultivate, and do their utmost to boost along the "Greater Production Movement."

In places where it is not feasible for employees to utilize arable land along the "Right of Way," the owners of property adjoining are urged to make proper use of it, not for pasture or grazing, but for the purpose of raising such crops as will materially add to the food supply.

The question of food is vital and pre-eminent. Next to munitions, the Allied countries need food. Everything in the way of food that can be grown is an important contribution to the Empire's needs. Whatever is raised for home consumption releases as much more for export. If our people generally raise their own potatoes and garden truck, the farmers will raise more oats and grain and buckwheat. On comparatively small patches of land enough can be grown to feed several people, and if many individuals make even what might be considered a humble effort, the total result will be of vast importance.

In many sections there is excellent land along the right of way. tI has been the practice in some localities for station agents and section men to utilize strips convenient to their neighborhood for garden patches, and for growing oats, hay and buckwheat or potatoes. Last year there was considerable gardening, but when the total acreage of land available is considered, the agricultural attempts were really insignificant. It is felt that many miles of this land could be brought under cultivation, and the railway is showing its earnestness in the matter by offering the use of whatever land is available along the right of way.

Applications for railway land can be made to the Superinitendent of the District. Preference will be given first to employees and then to the property owners adjoining. In cases where the right of way is through unoccupied land, any person who will guarantee a bona fide intention of raising crops may make application.

All enquiries regarding land permits addressed to the Railway will be promptly answered and the fullest information given.

DAIRYIN.G

MAMMITIS OR GARGET

The syllables "itis" affixed to a medical term mean inflammation of the part involved. Mammitis means inflammation of the mammary gland, or udder. Other examples are appendicitis, inflammation of the appendix; enteritis, inflammation of the bowels; nereitis, inflammation of a nerve; gastritis, inflammation of the stomach; bronchitis, inflammation of the bronchial tupes. Gaget is the term commonly used for mammitis, and should be taken to mean that trouble. Many dairymen, however, apply the word to the changed milk which comes from a quarter attacked with mammitis. They call the milk garget and the disease caked bag.

The medicinal plant known as poke root (phytolocca decandra) also is familiarly known as garget or garget root, for the reasons, we assume, that it is a popular and very valuable remedy for garget.

The Symptoms of Garget

Let it be clearly understood at the outset that there are several forms of mammitis, and that garget, as a term, should be applied only to simple mammitis, in which fever usually is absent and no infective process present.

Simple mammitis is characterized by swelling, redness, and comparatively slight heat and tenderness of the quarter attacked, or of the entire udder. Usually but one quarter is involved. The milk changes in consistency, becoming thin and containing clots, as whey separates from the coagulated milk or curds. The milk does not have a bad odor and does not contain pus. The cow rarely has fever, does not, as a rule, lose appetite, nor is she noticeably lame, but she may show slight straddling or stiffness of the hind legs. There is a considerable shrinking in milk, but in some of the mildest attacks the swelling quickly subsides and the milk again becomes normal in consistency, appearance adn amount. The latter cases are the most pu zling, as no cause is apparent.

In more severe cases blood may be found in the milk, hard lumps form in the quarter, tending to remain permanently, and secretion of milk subsides or gradually lessens. It is common to find in even the apparently recovered quarter that the gland tissue has thickened and hardened. The reason for this that true secreting mammary gland tissue has been wholly or partially replaced by tumor or scar tissue, and where this has occurred the cow will be subject to a worse attack at her next calving, or following any influence that commonly causes garget.

It should b eremembered, too, that simple mammitis improperly treated, and sometimes in spite of the best treatment that can be given, tends to assume the graver destructive form termed acute, infectious, or purulent mammitis (or mastitis). There is also a form known as contagious mammitis, and the infective forms may end in gargrene, which often proves fatal.

Common Cause of Garget

In many instances no cause can be assigned for an attack of simple mammitis, but in our experience it usually is blamable to one or the other of the following causes: Chill, bruise, or other injury to the udder; sudden change of feed; excessive use of protein-rich feed; rough, irregular or incomplete milking, often resulting from a sudden change of milkers; coming in heat; indigestion from any cause.

The more severe forms of mammitis are caused by infection from germs which enter the milk duct of the teat, or find entrance at a wound, or spread inward from a sore on the tip of the teat. Infection often is carried by the milker's hands, introduced by a milking tube or other instrument, or contracted from a contaminated floor, gutter, yard, pond or mud hole.

Measures of Prevention

Carefully avoid causes mentioned in the foregoing, and, in addition, that all forms of mammitis may be prevented endeavor to maintain sanitary conditions about the cows. The average dairyman who also is his own farmer and often his own chore boy, cannot well wash the udder and his hands before milking each cow, but he can at least wipe the udder with a clean, damp cloth, and see that his hands are clean and finger nails trimmed before starting to milk. These simple measures pay well, for they will tend to prevent many a sase of garget. It also is a comparatively easy and practicable matter to keep the stall floors clean and freshly bedded, and to prevent the cows from dragging their udders through filth and mud on their way to the stable and to have the stanchions so adjusted and the stall floors of such width that cows will not trample upon one another's teats.

Another preventive measure, which we have often introduced with good results in stables where slight attacks of mysterious garget have been prevalent, is the careful stripping of the udder of each cow by a special milker a few minutes after the regular milker is done. See to it also that cows do not lie upon hard, cold cement floors. Cover at least the rear part of each stall with cork brick, or boards which are to be kept clean and well bedded. Lastly, instantly isolate a cow when anything goes wrong with her udder and keep her isolated until perfectly recovered. Also milk such cows last, or, better still, have them milked by one who does not milk the well cows. Were this made the invariable rule in every dairy stable, mammitis, which at present is a terrible scourge in many dairies, would become less common and far less ruinous in its attacks.

Treatment of Simple Mammitis

Methods of treatment are many and different, and what one man considers all right another calls all wrong. Veterinarians, too, differ in their opinions upon the subject, and in their methods of treatment. Forexample, some strenuously object to the administration of aphysic, while others believe in a physic. Some advocate inflating the udder with air solutions, while others decry such measures. Each dairyman and practitioner has his favorite method of treatment. We cannot, therefore prescribe a method of treatment that will be approved by everyone, nor is that posible in prescribing for any diseases. We can, however, confidently offer a few hints on treatment which experience has taught us to be sane, safe and satisfactory.

The first bit of advice we have to offer is that treatment, to be effective, must be instant, thorough and persistent. Delay spells disappointment and disaster. More can be done in the first 12 hours of treatment in every case of garget than in all time afterward. Unless immediate and perfect recovery results from treatement, the utility of the cow is seriously impaired anad recurrence of attack almost certain.

The second suggestiin, and of about equal importance, is that all fluid should be gently stripped from the udder every two hours. Next in imsage of the udder tigether with hot fomentations (bathings), and applications of sothing and slightly stimulating lotions or ointments.

The Medicines to be Used

Facetiously speaking, elbow grease is most commonly adivsed, and there is no denying that massage, already prescribed, is of supreme importance At the outsct of an attack we believe in giving a full dose of epsom salts, and following it twice daily with from one to four teaspoonfuls each of powdered saltpeter and poke root administered i nany way found most convenient.

Local treatment consists in supporting the swollen udder with a bandage around the body in which may be packed spent hops or cotton waste to be kept saturated with hot water, or a poultice of hot cookel oatmeal. If help is available, constant fomentation of the udder with hot water will usually do more good than a poultice. Frequent massage of the udder with the palm of the hands upon which oil or vaselinie has been applied will be found beneficial, not forgetting frequent stripping away of milk or other fluid.

A mixture of one teaspoonful each

of turpentine and fluid extracts of belladonna leaves and poke root with two tablespoons of lanolin or lard will be found effective. Rub it in twice daialy. If hardnesss of the udder remains after the acute inflammation subsides, rub in iodine ointment once daily, and if that does not give satisfactory results, sbubstitute a mixture of one part of mercurial ointment and three parts of lanolin, lard, or soft soap.

UDDER AND TEATS NEED GOOD CARE IF AILMENTS OCCUR

Whether it is a beef or dairy type of cow a healthy, well balanced udder is an important feature. Many men, over-confident of their ability to select good cows have passed poor judgment because they slighted this point of all points. Examine the udder carefully, milk the cow and satisfy yourself that the quarters of her udder are all healthy and working properly.

Comfortable stalls and standing platforms are an important factor in preventinig injuries to the cow's udder and teats. Provide plenty of room for the cows to lie down and stand up without stepping on the teats or udder of the cow in the next stall. Build the platform long enough so that the cows can lie down without their udders hanging over the sharp edge of the planks or concrete. At calving time put the cows in box staalls where they can step about, lie down and get up without bruising their udders.

One of the most frequent causes of caked and inflamed udders is too much feed of the wrong kind the few weeks before calving. If the feeder knows how to feed and care for dairy cows there is but little danger of udder troubles. When cows are fed heavy rations of grain right up to the time parturition there often follows troublesome sieges of udder ailments. As a rule successful feeders prevent their cows from having caked and feverish udders at the time of calving by feeding and handling them in the right way. No harm will result from feeding libe al grain rations, if the cows need it, up to within two or three weeks of calving, but after that time it is better to reduce the grain ration and feed more silage, clover hay and a little bran and linsedd oilmeal. Even the rations of silage should be cut down one-half for a few days previous to calving. but hay should be fed liberally. all the cow will clean up. After calving, bran and small quantities of oilmeal may be fed in moderate quantities for a few days.

A warm bran mash with a few whole oats and a little oilmeal in it is one of the best feeds that can be given a cow shortly after calving, for these feeds tend to put her digestion in good condition. The bran is light and laxative, the oats are one of the best fees to strengthen the reproductive system, and the oilmeal is laxative. Such feeding gives better results than dosing and doping with Epsom salts and linseed oil. Further, a pail of warm water, especially in cold weather, is very desirable for the cow's system is likely to be a little feverish at this time and demands water. In summer water from the water basins or stock tank may be used, but too much cold water should never be given a cow at the time of calving, as the chilling effect of the water is harmful.

All heavy milkers sould have good care and proper attention should be given to the care of the udders immediately after calving. Manipulating the teats and udders with the hands and drawing the milk carefully is preferable to allowing the calf to nurse. Warm water is an excellent remedy for caked udders, and carborated vaseline is one of the best remedies for sore and chapped teats. If the condition of the udder is not improved by bathing in warm water and maipulating it with the hands, rub in some lanolin (wool fat) with some belladonna or camphor added. Keep the cow in a warm, well bedded stall and see that she is milked regularly and carefully. Unless the congestion is relieved propmtly it is very apt to develop into more serious trouble and the loss of one or more quarters.

As the milk glands are under direct control of the nervous system it is always better to avoid any excitement or conditions which affect the nervous system and re-act upon the milk-producing glands. Any undue disturbance of the normal distribution of the nervous force will divert some of the blood supply from the milk glands to some of the other parts of the body and diminish the milk flow. The well known phenomenon of "not giving milk down" the milk is the milk is the result of the nervous tone in the gland brought about by some sort of excitement. Unless the cow is comfortable and in perfect repose the secretion of milk will not take place normally. The lesson to be derived from this is that the cow should be treated with kindness and kept free from excitement.

An injury to the udder from a blow or a puncture by a snag is almost sure to prove serious unless prompt treatment is given. To prevent infection and reduce inflammation the writer has had good results from using tincture of iodine, followed with vaseline. The vaseline prevents the skin from becoming dry and cracking. The same have proven effective in treating, wounds to the teats. For scratches or cases of chapped teats the use of carbolated vaseline is preferable especially when applied by the average dairy farmer.

Severe cases of garget frequently result from neglecting to give the udders and teats proper attention. Dairy farmers should endeavor to prevent this infection from getting in their herds or spreading from one cow to another in case they have one or two cases. If you have suspicion that a new cow or any member of the herd is infected she should be isolated, milked by someone who does not milk any of the other cows and given good care. And be careful not to use a milking tube unless it is absolutely necessary, and see that the tube is properly sterilized and disinfected every time it is used. Many feeders get good results fro mfeeding one-half ounce doses of hpposulphite of soda once or twice a da yto a cow suffering from an infected udder. As a rule garget can be held in control by effective preventitive measures. Give prompt attention to the cow the first time you notice anything wrong with her udder or teats.—C .F.

GIVE THE COW A REST

Milk from cows which are milked rigth up to the time of calving frequently has an unpleasant odor and an animal-like taste, or may even be salty or bitter. For this reason, and because the udder and other tissues vital to maximum milk production should have an oportunity for rest before a new period of lactation begins, all milk cows should be "dried up" at least one month before parturition is due.

THE "ACID" TEST OF VALUE

At an auction sale the buyer makes the price.

Auction prices are apt to be lower than the real value warrants, rather than higher.

In any case, auction prices represent the estimate of value placed on the article by the buyer and not the seller.

During the past few months, the cow owner's appreciation of the unusual values offered in De Laval Cream Separators has been demonstrated in a most remarkable way.

From one state after another have come reports of the sale of De Laval machines at farm auctions—machines which had been in steady use for several years—at prices, in most cases, only two or three dollars less than the sale price when new; sometimes at practically the same price at which the machine was sold when new; and, in several instances, at even more than the original list price.

In February, at a Missouri auction sale a De Laval in use two years was sold for $1.25 above the original purchase price. In Kentucky a farmer paid for a De Laval $2.00 more than the original price, at an auction sale. Last January, in West Virginia, a second-hand De Laval sold at auction for $2.50 less than the original catalog price. On January 15th, in Ohio, a De Laval machine in use a year was sold at auction for exactly the same price it brought when new, and at another point in Ohio a De Laval in use several months brought several dollars more at auction than the original list price. In the province of Ontario, early in April, a De Laval in use since 1916 brought at auction a price $5.00 higher than the owner paid for it when new.

In contrast with these prices paid for De Lavals at farm auctions, it is interesting to note that when other makes of cream separators are offered they are usually listed simply as a "cream separator," and not by name. Often there is no bid for such machines and their usual auction prices run from $10 to $15. We have never heard of one that sold at auction for half its original cost.

Perhaps you may not have had an opportunity to learn of the cleaner skimming, easier turning, the great durability and the splendid service given by the De Laval machines, but here is the strongest and best sort of evidence that those who do know cream separators appreciate that the man who buys a De Laval gets good and generous value for the purchase price. Ann further, that even after a De Laval has been several years in use, it is practically as good as new.

If you are without a cream separator or in need of a new or better one, why not see the local De Laval agent immediately? If you don't know him, address the nearest De Laval office as below, for any desired particulars.

SOME COMMON DISEASES OF DAIRY CALVES

A very large percentage of all the calves that are raised for the dairy go wrong during the first few months of their career. This is usually the result of ignorance of the needs of a calf on the part of the dairyman, or neglect to comply with what he knows are imperative demands in order to insure success.

Calves brought into the world by healthy stock are almost invariably well born; in other words they are healthy and in a position to go on and make good. Unfortunately, however, all dairymen are not watchful as to the calf's condition and careful to supply its needs.

Calves allowed to run with their dams and get their food in the natural way are rarely sick, and in order to get the best results in rearing these young things it is best to follow as closely as possible the natural methods

Good calves can be raised by hand, but unless great care is taken to have the food approximate to that of the dam's milk and other conditions relative to cleanliness of utensils and quarters in which they are kept, sooner or later troubles of one kind and another will be the inevitable result. By following the correct methods in the practice of raising calves, it is quite easy to guard against most troubles that cause loss in this kind of stock. On the other hand, however, carelessness or indifference will just as surely bring disaster and render the business unprofitable.

Indigestion

Indigestion is perhaps the most common of all diseases that afflict the calf and is almost invariably caused by a bad system of feeding. Many farmers take the calf from the cow at once after birth and teach it to drink; give it half a dozen feeds of milk from its dam out of a clean or dirty pail, cold or warm as the case may be, and then put it on skim milk. This treatment is practically sure to bring on the above mentioned disease.

The symptoms vary somewhat according to the cause. General unthriftiness is sure to be one of the signs of this trouble. In addition there is likely to be more or less constipation, folowed by diarrhoea. If the calf does not get relief it may drag along for some time, but is liable to drop off at any minute.

In tre treatment of this disease the first thing to do is to correct the feed. Nothing of permanent benfit can be done for the poor creature until it has been put on a reasonable ration. The calf may be one, two or three months old and should be on quite strong feed; but even so it is best to go right back to the beginning again, commence all over and begin right. Put it on a new milk diet and keep it there until it is gaining nicely. Before commencing on the new ration, however, it is best to administer from two to four ounces of castor oil to calves from one to two months old.

After they begin to gain nicely, put a litle linseed or flaxseed meal in their ration and substitute a small quantity of skim milk, increasing it each day, and reducing the whole milk until in about two weeks the calf is getting all skim milk. Now keep on with this, at the same time adding laxative and easily digested food, making all the changes gradually.

Scours

This disease while being frequently the direct result of indigestion brought on by bad feeding, is not always caused in that way. It may be brought on by exposure to cold rains, lying on cold, wet ground, suddenly changing the food, or it may be the direct result of contagion from disease germs such as white scours.

In any case the first thing to do is to find out the cause and remove it. If it is indigestion, correct the ration; if it is exposure, keep it in a warm, dry place, and if it is white scours the treatment must be quick or you are likely to have a dead calf on your hands. For any of the different phases of this disease give a dose of castor oil as recommended for indigestion, and for white scours add one dram or one teaspoonful of tincture of laudaunm. If this does not give relief, give the following: Tincture of laudanum one dram, lime water 2 ounces or 4 tablespoonfuls. Give as a drench in a little warm milk three times a day until relieved.

Constipation

This trouble in calves is almost invariably the result of improper feeding in much the same way as indigestion. The milk is frequently taken away from them when altogether too young, coarse, dry, indigestible and innutritious food is given and not enough liquid is taken into the stomach to supply the needs of the body.

The remedy is to give a dose of castor oil or raw linseed oil to get rid of the old dry mass, and then feed on succulent, easily digested and wholesome feeds suited to the age and development of the calf. When suculent grass is available and the calf is two months old, let it out during the day to feed, putting it in at night if the ground is wet or cold. If it is winter, feed bran, linseed meal, roots, ensilage, fine clover or alfalfa hay and like feeds that will have a soothing effect on the bowels. Plenty of pure water should be at hand at least three times a day, and better still, all the time if convenient. Warm the water a little and the calf will drink all the more of it.

Lice

These pests are very troublesome in young stock, particularly those a few months old that are not thriving well. For this trouble mix one part of helebore and four parts of fresh Portland cement together, and with an old pepper box or small tin can, with holes punched in the lid, sift it on from head to tail along each side of the spine. Repeat in a week or ten days.

Ring Worm

These are caused by a tiny insect that burrows in circles in the skin, destroying the hair.

For this use citron salve, rubbing in a small piece over the spot and into the surrounding hair. Rub it all in as it is poisonous. One aplication is usually sufficient. Another remedy is crude petroleum oil aplied to the spot with a brush three times a week until a cure is affected.—W. J.

BREEDERS OF DAIRY CATTLE WHO HAVE MADE A SUCCESS HAVE BEEN GENEROUS FEEDERS

The question as to which breed will prove the most profitable from a breeding standpoint involves several important questions, besides that of the relative efficiency in the production of milk and its products Apart from the importance of adaptation of type to local conditions there is a great advantage in community breeding. If the dairy farmers of an entire community are interested in producing pure-bred cattle and grades of a single breed that is well adapted to the conditions the region becomes known as a place where such cattle an be purchased both for breeding and commercial purposes. Hence all of the surplus stock can be sold at higher prices and with less expense for advertising than if only a few of the dairy farmers were breeding the one breed. Success in breeding registered cattle is much easier when one is located in a community where a number or progressive dairy farmers are working with one breed.

Few Good Females Desirable

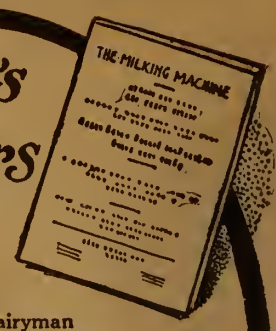
In buying foundation femaels for a herd, individual records as well as approved blood lines should be given as much attention as age or price. As a rule, other factors being equal, it is better to buy females of breeding age, either with calves at foot, or safe in calf to sires that are bred right to nick with them. When one gets a good young cow with a creditable milk record he is getting something for his mone. One eliminates risk, depreciation and uncertainty; and makes a fair start toward making the business pay. Many a breeder has made a good beginning from the purchase of a few old cows. It is the old cows that many experienced breeders prize so highly. A close study of the prominent dairy performers, looking up the age of their dams, would be enlightening as well as interesting to many breeders who think it good management to sell their best cows before they grow old in their herds. To secure a few head of desirable females means a lot of hard study and close investigation, but unless a man will go about the proble mintelligently he had better keep his money in the bank and devote his energies to some other line of farming.

A Tried Sire is Preferable

The greatest improvement in breeding must come largely through the bull. As a rule, the tried sire, one that has served his time in some established herd and is being sold to make room for one of leser age, is a safer nvestment than a young animal. By studying the form and character of some of his offspring one can form an accurate idea of his value as a sire, and there is less risk to run than when a perfectly untried sire is purchased. When an old sire is selected, the beginner will be assured of a certain degree of success until he has got his bearings and become sufficiently familiar with the type and character of the animals of the herd with which he is working to select the sorts that find favor among the most liberal buyers. From any point of view, the use of a tried sire is preferable. He will prove an anchor in time of trouble.

One of the country's most famous breeders owes his success to the use of one excpeionally good aged bull. He has been searching for several years for another bull that will prove equally valuable as a sire. It is the well defined conviction of the owner that he must secure a sire whose calves will be as meritorious as those of th eone used so long or else his herd cannot be kept up to its present high standard. This breeder, who won fame and fortune through some of the heavy milking daughters of his famous sire, has more of a problem than merely replacing the bull that has done son well a sa sire. He must find a bull whose characteristics and triats nick well with the females of the first great sire. This makes the situation omre perplexing, but the owner is seeking diligently, studying good bulls and consulting milk records and experimenting with a number of young bulls in a moderate way to find out what kind of daughters they will produce. No doubt before the old sire shall have outlived his days of usefulness a worthy young sire will have been discovered. The real value of a tried sire in rounding the corners, so to speak, of a herd of cows from vari-

The Government's Advice to Farmers on Cows



In the interest of every farmer and dairyman the Dominion Government has issued a special circular pointing out the value of the Milking Machine under the present conditions of labor on the farm.

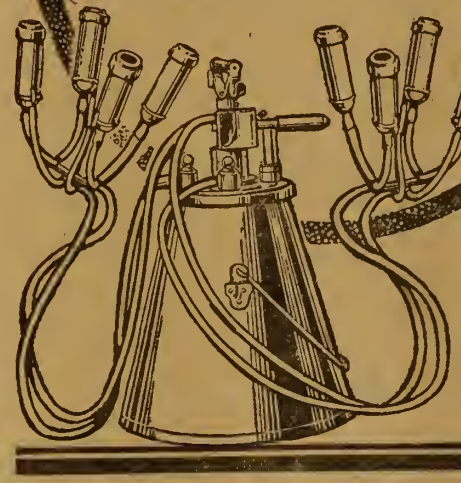
Mr. J. H. Grisdale, B. Agr., Director of the Dominion Experimental Farms says, "The present is no time to let things stand in the way of increased production, and every farmer with a herd of twelve or more cows should seriously consider the installation of a milking machine. Three years' experience of mechanical milkers on the Central Experimental Farm shows that cows do not dry off more quickly than when milked by hand. Cows have no more objection to being milked by a milking machine than to being milked by hand."

The experience of an ever increasing number of farmers, backed by the opinion of the leading Experimental Farms and Stations prove that

EMPIRE MILKING MACHINES

increase production and save money and time, one machine doing the same work as three hired men. On account of its simplicity, a boy or girl can operate an Empire with ease—doing the work with uniformity and without injury to the cows.

You can help the cause of the Allies by keeping and enlarging your herds despite the shortage of labor. Empire Milking Machines will do the milking for you, cheaper and quicker than hired men.



Write us for fuller information on this important subject, and learn also how to do away with drudgery on the farm.

Write for Catalogue, K

ous breeders and placing the new breeder in posession of a herd of females that present much uniformity of type and quality can hardly be measured in dolars and cents. It is only thus that a beginner may succeed in developing his herd to a standard of high excellence unless he should have the singular good fortune to obtain a young bull that proves to be one of the really great sires of the breed.

The Test of Efficiency

The breeder must make a constant study of the essential merits of breeding animals and familiarize himself with the general type and minor characteristics of his animals in order to render them suitable for the persons into whose ownership they ultimately come to perform their service. The cow that shows a profit at the end of the year gives more real satisfaction than a phenomenal producer who does her work at a loss. The dairymen's ideal of perfection is sure to be the cow that gives him the best returns consequently she must not be a large producer but an economical producer. In judging pure-bred dairy cattle for what they will produce, ancestry must be weighed to an extent of at least fifty per cent. of the whole. To the man who keeps a sire or dam for producing young, a knowledge of pedigree is of as much importance as the make-up of the animal itself. Estimating the value of pedigree will always be a determining factor in breeding pure-bred cattle, and the greatest success will be achieved by those who master and utilize this knowledge and who do not lose sight of the pedigree's best proof, the make-up of the animal itself.

Careful selection of the sires and dams influences the heredity tendency to produce larger milk and butter yields and good breeding stock. A liberal system of feeding and suitable environment develops these inherited tendencies. Heredity is a peculiar force. We can use it to do some things, we can head it off and prevent it doing other things we do not want it to do, and it frequently does things that no one can acocunt for. Much that appeals to the eye or goes to make big records is caused by what goes into the mouth. Good breeders who have made a success have been generous feeders. Feed is not all, for there are many cows that can not return a profit under and system of feeding. It is the breeder's duty to weed out all of the unprofitable cows by the process of elimination. Good breeding must be reinforced by generous feeding to bring out the best that is in animals.—W. M. Kelly.

THE SALE RING LIKE THE SHOW RING MUST HAVE THE ANIMAL IN FIT SHAPE

good bull is more than half the herd and a poor bull is the whole herd." This remark came from Prof. E. S. Archibald, Ottawa Valley District Holstein Breeders' Club, when asked to express his opinion on the subject of the "foundation cow." He made the piquant remark that the cow that was brought into the sale ring, was the cow from which the young buyer had to start his herd. He deprecitaed the practice of entering at consignment sales the valueless cow. "Bring your good cows to the sale and it will uphold the breed character. To bring such trash to a sale makes short life and quick death to the sale organization." He advised the Club to take precautions to keep non-type and non-record cows out of the sale ring. The animal or herd representative that tops the sale is the animal fitted for sale. The best sales of the past years were those that had their consignments guaranteed against tuberculosis and abortion for 60 days. The sensational Holstein or Shorthorn sales of the past, that drew crowds of buyers from all over the American continent, was simply due to the quality of the stock advertised and the guarantee each animal caried with it. "It is one of the duties of the Club," he said, "to take initial steps to organize the character of the sales and make it one of the fundamental principles in the conduct of their business."

In answer to some questions asked him in regard to the principles of breeding from cows that did not conform to every detail of confirmation of character, he said that "no one can take chances on a weak and poorly shaped udder even though the cow had good conformation. The udder was the place where the milk was manufactured. A shallow cow with a good udder was a better choice, but the shallow cow was apt to be a flusher." He advised to go after the cow that neither of these faults; they will not make good foundation cows. "Breed the durable farmer's cow; no other way will lead to tth euplifting of the breed or its utility. The pure bred cow must be the commercial cow and al else should be discounted with the breeder of pure bred Holsteins."

THE DAIRY BARN'S FOUR MAIN CORNER STONES

In the construction of the dairy barn there are four points that are of very decided importance. These are real fundamentals from the practical standpoint. In the first place darinage is imperative. Have the barn so located that the natural drainage will keep the yards and surroundings free from the slop and filth that are inevitable where water is allowed to accumulate from the eaves with every rain. If there is no natural location that provides this perfect drainage, make a location by grading.

The second point from the natural standpoint is a location that provides sunshine in every quarter of the stable. This may seem impossible from the absolute standpoint, but is is possible to provide such an abundance of windows and to have the barn so situated that there will be sunshine in some part of the stable during both afternoon and morning.

A third point is the method of construction. Each man may have his own pet ideas as to the form of the barn or the building material to be used or the particular shape and arrangement, but with all of this one must remember that the stable is often a source of bacteria contamination and ti may propogate disease to a very rapid extent, if it is so finished that filthy slovenly conditions prevail where the cattle stand. Keep the barn in such a way that it can be easily cleaned, that it will be easy to produce clean milk therin and that it will be free from all nests and places that harbor disease germs.

Finally, the dairy barn sould be provided with thorough systems of ventilation. Fresh air is the cow's native right just as it is the native right of the human being. It is unnecessary to have your stable so foul that wehn you open the door in the morning the air is almost overcoming simply because it has been closed for the night. A stable may be just as warm when flooded with pure air as it is when sealed up heremetically. As a matter of fact it is warmer and far more comfortable for there is nothing to be gained by forcing a cow to breathe the same air over and over again. It becomes overburdened with impurities and is a regular hotbed of disease.

A TRANSFORMATION

"Mr. A. C. in 1915 sold some poor cows, again in 1916 he sold his five poorest; he has fed better, has put in a silo, and has a goo dsire. From being one of the poorest dairymen in the section, he will now rank among the best." So writes a keen observer of dairy progress in Quebec.

From a yield of 3,021 lbs. milk in 1915, the above dairyman increased the production of ten cows to 6,246 lbs. milk and 236 lbs. fat in 1917.

How did h eknow which cows to keep, which cows to sell? The answer is very simple. He kept dairy records, weighing the milk of each cow night and morning every tenth day, right through the lactation period, so that there was no mistake about it. He also found that it pays to feed well and grade up.

Consider that milk yield a moment: from three thousand up to over six thousand pounds, doubled in three years; what a transformation! That's real encouragement, better returns for labor, more cash, more home comforts, more real use to humanity.

Yes, of course his experience can be duplicated. Just write to the Dairy Commissioner, Ottawa, for milk record forms, they are free, and get started weighin right away, as soon as the first cow freshens.—C.F.W.

A silo that lives up to its name

I D E A L

YOU should exercise just as great care in choosing a silo as a cream separator.

You can afford to have none but the best.

You want a silo that gives you the best silage.

You want a silo that's durable—one that will last the longest; one that is the most economical in the long run.

You'll never regret buying an IDEAL GREEN FEED SILO

When you consider that the average life of an IDEAL is from 15 to 20 years; that it pays for itself the first year and that each year thereafter it earns for its owner a profit equal to its first cost, you will appreciate why the IDEAL is the best-paying silo you can buy.

Now is the time for you to install an IDEAL. Summer will soon be here and you'll have so much work to attend to that you'll have little time to think about silos. Why not look into the silo question now before you get so crowded with work?

Write today for our book, which not only explains in detail the advantages of using the IDEAL but gives much valuable information about silos and silage.

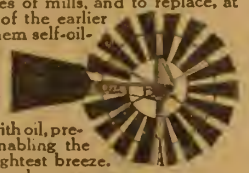
THE SELF-OILING WINDMILL

has become so popular in its first three years that thousands have been called for to replace, on their old towers, other makes of mills, and to replace, at small cost, the geaning of the earlier Aermotors, making them self-oiling. Its enclosed motor keeps in the oil and keeps out dust and rain. The Splash Oiling System constantly floods every bearing with oil, preventing wear and enabling the mill to pump in the lightest breeze. The oil supply is renewed once a year.



Double Gears are used, each carrying half the load.

We make Gasoline Engines, Pumps, Tanks, Water Supply Goods and Steel Frame Saws.

Write AERMOTOR CO., 2522 Twelfth St., Chicago

THE HORSE

REARING HEAVY COLTS FROM MARES

There is perhaps no side line in general farming that under suitable conditions gives better monetary returns for the labor involved than the rearing of draught colts. Among the necessary conditions are, first, roomy mares of good quality with some draught breeding and weighing at least 1300 pounds; second, a chance for good pasturage, well fenced. The barbed wire fence is not a good one as risk of damage to colts is too great.

The mares above described will do the work of the farm and raise a colt yearly, if desired, with but little lost time at average farm work.

The type of sire available has a good deal to do with the profit to be realized from the colt. He, of course, should be purebred if consistently good results are to be expected. Conformation and quality are of more importance than his weight, though the larger he is if his quality is right the more valuable he should be. Whether he be Clydesdale, Percheron, Suffolk Punch, Shore or Belgian, his feet and bone must be good, his joints well formed and smooth and evidence of constitution and draught strength shown by his keneral conformation. The choice of breed is largely a matter of personal preference, but if all the farmers in a county or agood sized portion of it could only have the same preference and breed along the same lines, they could reap much more profit from their colts than where all the diereafft breeds are introduced. Better stallions could be obtained and much better markets got for the colts.

When a really good stallion can be obtained it will be more profitable to pay $20 for a service fee than $10. No stallion owner cann afford to put from $2 500 to $4.000 into a horse for the $10 fee. The best stallions of any breed cost within the above range and sometimes very much higher..

The time to breed is whenever it can be done. A good colt may be raised if dropped any month in the year. If it were possible to breed so as to have the colts dropped when the work was least pressing that would be the most profitable time. A comfortable box stall is needed for each mare and colt. The mare may work moderately up to time of foaling and after a week's rest after foaling can go into the team again without injury. She should not be overheated and the colt should be allowed an opportunity to suckle at least three times between 7 a. m. and 6 p. m. At ordinary farm work the loss of time for a mare in foaling and caring for the colt should not exceed $10 in cost.

From data obtained at the Fredericton Experimental Station, such a colt at three years of age, well broken and ready for business represents a total expenditure of—Service fee, say $15. Loss of time of mare $10. Feed for two years $61.51. Feed for third year $80.60. Blacksmith bill $10. A total of $177.11. Against this there is a credit for the work of the colt during the third year which at the Experimental Station was 100 days at 70c per day, leaving the net cost of the colt weighing 1390 pounds at three years old, $107.11.

At present these colts will sell at from $160 to $200 each.

TRAIN THE COLTS YOUNG

One farmer was visiting another; his team stood hitched. As he was about to start for home the neighbor said he would like to have some help in trimming the feet of a three-year-old filly whose hoofs had been let alone so far. This animal was barely halterwise and had never had her feet picked up before. So there followed a rough-and-tumble fight. The mare was "roped" and the rope burned her leg. She fought and finally backed into the hitched team, kicking them so that they backed into a wire fence. A general mix-up followed and for a while it looked as though both men and all three horses would be tied in a hard knot with barbed wire.

It was a dangerous undertaking, and the next hoof-trimming will not be easy either. But if the filly had been gentled while she was still in her baby days there would have been no trouble. We have two mare colts, one of the spring of 19'3, one born last spring. Both of them are halter-broken and the older one knows words of command, so that she will step up or over in the stall when spoken to. The old-colt is high-strung like her mother, but my daughter put the halter on first and coaxed her until she would lead. There was no fight, no danger, though the colt seemed to shed some tears. I mean it; her eyes really filled and watered the first time. The younger colt took it very quietly, for she is not so nervous, though the two are full-sisters. They have both had their feet trimmed a number of times; our soil sandy soil does not wear the hoofs much and frequent trimming is necessary. They may be curried all over and the feet picked up at an ytime. With tame colts like these therr is no "breaking" such the cowboys used to risk their lives in, sometimes spoiling a horse for life.

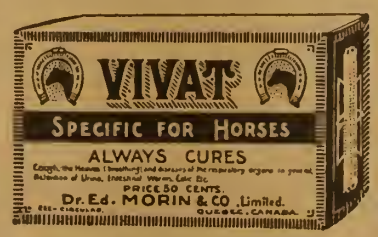
The Recognized Specific of Diseases of the Horse



A sovereign remedy in powder form which cures, Coughs, Heaves, Colic, etc. It strengthens the work horse as well as the race horse, and enables them to do more and better work. It has been successfully prescribed by many veterinarians notably by Dr. J. D. Duchene, in many critical cases, where results have proved remarkable.

A 50c box will be sufficient for six days' treatment.

DR. ED. MORIN & CO., LIMITED, - - Quebec, Canada

The older of our fillies will go into harness and carry a saddle this spring. She would have been taught now if the winter had not been so severe as to make outdoor work unpleasant.

One of my neighbors has a two-year-old mare that a ten-year-old boy rides and drives anywhere. She has always been handed by the children and does not know what is is to be afraid. Nothing ever hurt her yet, so she takes whatever comes as a matter of course. This family style of horse breaking is not so spectacular as that of the old range days, but it is cheaper, requiring no expensive saddle, no lariat, no whoops and yells, no quirt. It is more real fun, too, and makes a horse that will respond to 'whoa" when accidents happen. If the colts could choose there is no doubt about which kind they would favor.

Our younger colt was a little wild for a time owing to her mother's over-anxiety for her welfare. The mother's foolishness when a strange horse was brought into the yard resulted in a serious accident. She crowded her baby through a fence and it was cut badly. We brought the two into the barn and the men wanted to throw the colt so that we could stop the blood, I thought that would give her too much of a shock, as she was less than three months old, so I just followed her about quietly, putting on flour to stop the blood flow and finally getting her into a corner where is could throw a knotted bandage around the cut leg. Then she submitted quietly, as we let her stand close to her mother. The next day and while the leg was healing there was no trouble at all in handling her. That was all there was to her gentling and when her halter, a home-made one, made of an old pair of suspenders, was put on she took it as a matter of course, and followed wherever she was led.—Minnie B. Davis.

Horsemen Attention !

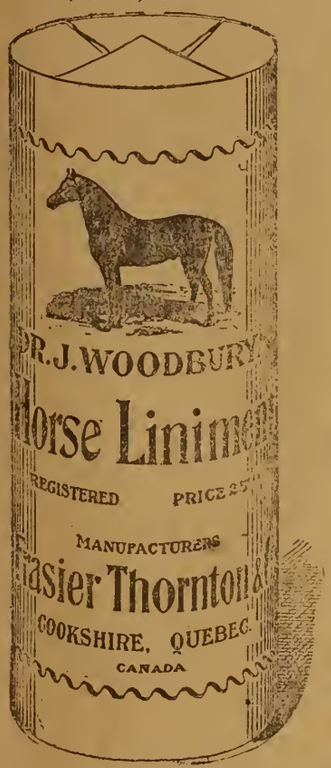
Dr. J. Woodbury's Horse Liniment and Dr. J. Woodbury's Condition Powders will save and preserve the life of your horses. Their use will cure and prevent the disease common to horses, such as Cough, Colds, Distemper, Spavins, Pinkeye, Splints, Curbs, Enlargements, Cracked Hoof, Kidney Trouble, Fevers, Cuts, Sores and will remove bunches of all kinds.

BEFORE USING

Why have a sick or lame horse, when you can get a reliable and warranted remedy? The leading horsement of the Dominion endorse Dr. J. Woodbury's Horse Liniment.

FOR SALE ALL DEALERS

PRICE 25 CENTS



Do you know that "Dr. J. Woodbury's Horse Liniment" is endorsed by all the leading horsemen of the Dominion. Save and preserve the life of your horses by its use. It will cure and prevent disease common among horses.

DEMAND
DR. J. WOODBURY'S
HORSE LINIMENT

AFTER USING

Use this preparation thoroughly for all and every disease of the horse for which it is recommended. Criticise it closely. Carefully watch, mark and notice, its effects, and, honestly judging it on its merits, you will be compelled to endorse it.

HOW WORMS AFFECT COLTS

As winter advances the damage from worms becomes evident in colts and horses. It is not because they have worms only at that time, but because the progressive infestation from tainted pastures or drinking water during the summer becomes more marked as the grazing season advances. Then as failing pastures and the change to the commonly poor quality of dry feeds causes a decline in the animal's thriftiness, the worms become more injurious. The extent of the injury from wrims is seldonm realized. If horsemen understood about it and were on their guard they would be saved much loss in values and be spared from the occasional actual deaths of valuable animals.

Most of the worms which affect horses are taken in by them with infested water or feed. Low, poorly drained, marshy or persistently damp pastures are very likely to harbor various sorts of worms to which horses are subject. When horses drink water from streams they sould be watched very closely for worms. There are some streams which have acquired a local notoriety because of the number of horses that die along their courses. Post mortems reveal worms.

Injurious results from worms are most common in colts and old horses, while those in the prime of life are able to endure their debilitating effects. The most commonly noted symptoms are white stains around the anus, an unexpected thriftiness, rough hair, loss of flesh, indigestion, anemia, tottering gait and sometimes colic. The absence of worms from the excrement is not an indication that the animal is free from them. Some kinds do ont appear and some others seldom do.

Various vermifuges may be used to clean out infested animals, depending upon the kind of worms predominating. Directiins for treating are frequently given in our veterinary columns. An almost miraculous change to a thrifty appearance and rapid gain in flesh frequently follow the eradication of these parasites. Prevention is beter. If horses have large pastures with good surface drainage and well water to drink they are not likely to become seriously infested with worms. If they must be confined to closely grazed small pastures an annual change to fresh ground is helpful. It is a notorious fact that horses do not thrive when crowded in small pastures even though the grazing is good. Doubtless worms are an important factor in such cases. .

CURING THE COLT'S CRACKED HOOFS

Due to lack of attention the fore feet of our draft yearling split badly when the colts were turned on pasture last spring. They carcked up the sides almost to the hoofheads and were spread badly. We hesitated about paring and rasping them, as we had never done this before and our father always said that the blacksmith would soon put the feet in shape when the colt was old enough to work and needed shoeing. But in this case we decided that something must be done, as the colt's feet were getting worse and he was beginning to show lameness.

Catching the yearling one morning, we quickly levelled the sole of the foot, using a heavy jock-knife, a blacksmith's knife and a rasp. The outside edge of the hoow was cut sort so that the pressure of the foot on the ground would not spread the hoofs. The outside quarter of each fore hoof was longer than the rest. It was spreading out and seemed to b ebreaking away from the wall of the foot. This was shortened so as to bear no pressure until the crack had time to grow out. About three weeks later the feet were rasped and again levelled. The cracks began to grow out at once and in three months the feet were sound and well formed.

This was the worst looking set of feet I ever saw on any colt. Two treatments with the knife and rasp put them in fine shape. So we have entirely abolishe dthe old idea that "the colt's feet should not be rasped until he is put to work." We are examining the feet of all our colts every few weeks. A few minutes with a sarp knife or rasp keeps them level and no cracks will ever be seen in them.—J. W. Henceroth.

WATERING HORSES

The stomach of a horse is extremely small, and therefore he should be watered at least three or four times a day, and if possible, should receive hay and grain three times a day. The less work he does the more important it is to give him hay often, because a hungry, idle horse is apt to take up some bad habit, such as biting, kicking cribbing or weaving. If he gnaws his manger or stall he is either hungry or wants salt. Salting is often neglected by many horse owners. It is a good plan to keep a lump of rock salt where the animals can get it when they want it.

PALMER'S
Summer Packs
for the
The "Soldiers of the Soil" recruits need Palmer's Summer Packs, or plough Shoes as they are often called, to keep their feet in good condition while doing hard farm work which their feet are not accustomed to.
Even farmers whose feet are hardened to farm labor find Palmer's Summer Packs very restful to tired, aching, burning feet. They are light in weight, roomy, pliable, comfortable, durable and waterproof.
Get a pair from your dealer. Look for the "Moose Head Brand"—stamped on every pair—a warranty of satisfaction.

POULTRY.

RAISING POULTRY FEED

In these days of high prices and scarcity, it is necessary that the farmer, instead of selling or killing off his poultry as no longer profitable to keep, keep his poultry and raise his own feed, or at least a good part of it. The poultr ymust be kept or the nation and the world will soon be without eggs, one of the most important food products of the farm, to say nothing about the meat of the poultry. This latter we can, if necessary, get along without, but most people would not care to if it can be avoided. Nor is it necessary, for it need not cost more to raise poultry and eggs than it does to provide other foods produced on the farms.

Farmers raise too little rgain—the most of them. If the right grains are selected, it is not difficult or specially expensive to raise good crops. Dent corn can be raised profitably on many farms, but not on all, and this should be planted and produced only where it can be done with satisfactory results. Oats may be raised almost anywhere if the proper varieties are selected and right methods used. In some parts of Maine, barley is easily and satisfactorily produced, and buckwheat nearly always proves a profitable crop under proper management. All these grains are suitable for poultry, and a satisfactory scratch food may be produced without difficulty by a proper combination of the varieties of grain that may be profitably raised in this climate.

A good crop of mangel beets may be kept in a moderately cold cellar and fed to and enjoyed by the poultry all through the winter. There should, of course, be a good supply of fresh Swiss chard and similar green food through the summer, and in the winter there should be plenty of small and unsalable cabbages, so that the hens may have all they want all through the cold winter. It is also best to lay aside some of the most sound of the oats that have been threshed in the fall to sprout during the winter. This is some work, but no great task, and the labor will be well paid for in increased egg production at the time when eggs are highest and most profitable.

About everything that the farmer is unable to raise is the grit and shell that are so essential to the welfare of the birds, and these have not suffered seriously in price through war conditions, for this sort of food does not require cultivation, and all the labor required is that used in crushing, shipping and packing. Water, too, is free for the effort of preparing and keeping the dishes clean and the labor of transporting to the desired pens. It should be remembered that the greater part of the eggs is nothing but water, and the owner or caretaker should see to it that the hens never lack for this very essential part of their living ration.

High prices of grain do not offer a great inducement to raise many chickens this spring, and if reports are true, comparatively few will be raised. Perhaps it is wise to cut down the number somewhat, but a wholesale reduction where it is possible to raise them will prove a mistake. Chickens will be very high this fall under the best of conditions possible at this time, and this will make them higher still. But the demand, it is said, will not be less than in former years, even at high prices, and those who do have chickens to sell will reap an ample reward. Our advice to all who can do so, would be to raise a few chickens, at least, and if they have the facilities and can get the food for them, to raise a lot. We feel sure that every chicken offered for sale next fall can be sold at a profit, either for food or for breeding and egg production.

The information now being sent out to farmers frequently by the experts at the University of Maine should be a great help to farmers and others who keep poultry, and if their advice is followed with care, failures in the poultry business, even under the adverse conditions which exist today, ought to be, and will be, we believe, very few and far between. Do not neglect the poultry industry, or any other farming industry, especially at this time, when we need every ounce of food that every farm in the country is able to produce. —H. L. Goodwin in Maine Farmer.

VALUE OF MILK IN CHICKS' RATION

The value of milk, whether it be in the form of buttermilk or as the soured product, is inestimable in the baby chick ration.

As a tonic it is unequalled; the medicinal effects of the lactic acid in the milk help to keep the young chicks in the best possible condition and the digestive disorders that cause at least 50 per cent o fthe mortality is thereby eliminated. The white diarrhoea organism which is present in every newly-hatched chick is killed before it gains a foothold and all spreading of that disease is held in check.

Some very successful poultrymen desist from giving the chicks any water for the first three weeks of their lives, but supplant it with milk, since a stronger and quicker growth may be attained when it is used. Invariably, it should procede the first feeding, but not before they are at least forty-eight hours old.

Milk when substituted for beef scrap reduces the expense, while the danger in feeding is cut to a minimum. Alternating sweet and sour milk will prove disastrous, as it has a tendency to upset the digestive system. Experiments have shown that the chick's appetite is greatly increased when some form of milk is fed and no ill results have followed. R. K. K.

WHEAT SCREENINGS

Wheat screenings furnish a very economical grain ration for growing chicks or laying hens, and can be purchased in wheat-growing localities at a very reasonable price. With plenty of grain coming to our local mill we are able to buy a fair grade of screenings containing over 60% of broken and shrunken kernels with perhaps 10% of the balance edible seeds at $1.25 per 100 pounds. Screenings at this price are a very good buy, and we have laid in an ample supply for the coming season. They will replace 50% of the mixed ground feed for chicks over four weeks of age and at less than one-half its cost.

We feed the screenings in the brooder litter to encourage exercise or they can be thrown upon the ground out of doors or fed in troughs or hoppers if desired. A wholesome chick feed can be prepared at home by mixing together 100 pounds of screened cracked corn, 200 pounds of wheat screenings and 50 pounds of hulled oats or steel-cut oatmeal. The dirt and chaff in the screenings do no harm, for chicks one month old and over will pick out only the edible portion and leave the balance.

The edible portion of wheat screenings can be easily tested by putting a certain quantity, say two pounds, in a deep box before growing chicks or adult fowls. After they have picked out all they want weigh the remainder and the per cent of wholesome feed can be easily computed.—Maurice H. Decker.

HENHOUSE HINTS

Your poultry houses should be well ventilated in summer. Every glass window, cloth curtain, and board door should be left open night and day or removed until cold weather. It will require only a few minutes to do this and it will contribute much toward the comfort and best welfare of your hens. During warm weather it does not matter which side of the house is open, it would be better if all sides were out. There is no danger from drafts during August and September. Growing chicks will grow best when they can roost where there are clean perches and only a roof over their heads.

With this simple arrangement there will be less danger from crowding and mites. These mites or spider lice multiply very rapidly when the roosts are neglected. You will find them under the perches and in the cracks and crevices of the adjoining wood work. They crawl out of their hiding places at night and suck their fill of blood from the birds on the roosts. You can often detect them by a very disagreeable odor which they throw off.

In order to get rid of them the house must be opened up to the air, brushed and cleaned out thoroughly from ceiling to floor and then sprayed with a solution of creosote oil and water and then with whitewash so as to know every part of the house has been covered. If a dirt floor, 5 or 6 inches of the top must be removed to make a complete job of housecleaning. Those who keep poultry and neglect to keep them clean and comfortable cannot expect them to be profitable.

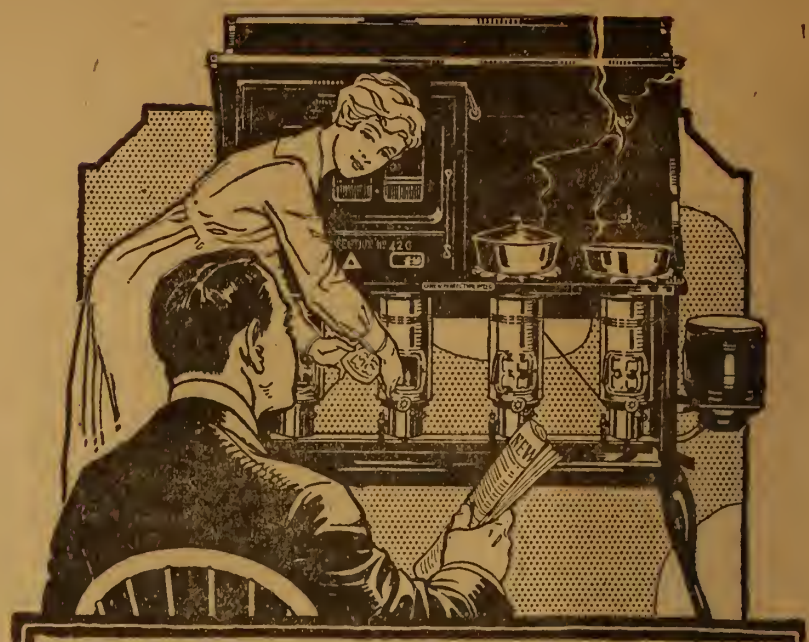
MITES IN HENHOUSE

Because red mites secure their food from the hen's body at night and hide on the roosts and in cracks in the daytime, they are particularly hard to destroy and must be constantly fought to be eliminated. If the mites are numerous an examination of the hens at night may reveal fowls to be fairly alive with them, while in the daytime they will be almost free from them. The bright red color of the mites is due to the blood which they have sucked from the body of the hen.

In the daytime practically all the mites will be hiding on the perches and cracks about the poultry house; the application of boiling water will be effective at this time. After the water is applied spray the perches and dropping platform with creolin or zenoleum. If crude oil is available the perches should be painted with this material frequently. The nests should also receive attention.

CARE OF YOUNG TURKEYS

Turkeys are, as a general thing, very hard to raise, but this is due mostly to carelessness and ignorance of their nature. Small turkeys and their mother should be given a large well-ventilated



COOKING IN COMFORT, AT LAST!

"WELL, no more coal or ashes to bother about now. And if my eyes hadn't been opened, you would still be cooking on the coal range all through the summer."

Husbands and sons—if you had to do the cooking, wouldn't you like to do it in the most economical, most efficient, simplest way possible? Save your wife or mother further fuel worries. Buy her a New Perfection Oil Cook Stove—It will mean better cooking, a cleaner, cooler kitchen and less work for her—and for you, economy, comfort and no waiting for meals.

Select the style now that suits the individual need of your home—one, two, three and four burner sizes. Be sure it's the stove with the Long Blue Chimney—and that it has the Cabinet and the New Perfection Oven. They make the stove complete for year-round cooking service.

Royalite Coal Oil gives best results.

coop on dry, well-drained ground.

Poults should not be fed until they are twenty-four hours old. Their feed should consist principally of dry grain, chick feed (that is clean and bright) milk (sour o rsweet), grit, plenty of green grass and some vegetables (such as onion tops). They should have fresh water every day.

Turkeys must have absolute cleanliness, fresh green grass to run on and must be kept free from lice by dusting insect powder in teh plumage of the hen and applying vaseline on the heads of the poults. They must have free range so they ca nhunt for insects for they have a wild, roaming nature.

DISCOUNTS EARLY MOLTING

Early molting of laying hens has been the recent topic of investigation by the agrichlthral department of New South Wales. The result in general agrees with recent American opinion that the various devices for forcing hens into early molting are not followed with satisfactory results. In fact, the reverse is often the case. Early molting hens are inclined to be poor layers for the most part, and some are inclined to molt twice, the second time at the first touch of winter. "Such get-rich-quick notions," comments the erport, "are generally heavily discounted by nature, and the beginner should shun all such, and begin along the lines of common sense and reasonable expectations."—George B. Fiske.

DON'T BOARD ROOSTERS

A great many farmers fail to realize that when they keep a lot of roosters around the place, they are supporting a number of non-productive boarders. Hens lay better without the roosters, and the eggs, being infertile, are very more easily kept and will last for weeks even in warm weather, where fertile eggs quiikly spoil. After April 20th, hens can again be put on the market for sale, and every good farmer is urged to sell his old hens and save the young phllets for laying fall eggs. Ship the cockerels to market promptly.

DUCKS AND DANDELIONS

Five ducks were premitted to have free access to a lawn 50 ft. by 150 ft. during the summer. At the end of the season the dandelions had been entirely suppressed without injury to the lawn, and did not come in again until the third season following.

The ducks were said to eat off not only the tops, but to grub out the roots to some extent. More ducks and fewer dogs should constitute a good food conservation motto at this time.

MAKE EVERY CHICKEN COUNT.

The aim this year should be to make everything count. Make every hen lay her best, make every chick mature early enough, and thereby make every pound of feed give the maximum returns.

Hatch Early.—Make every effort to get your chicks out this Spring before the first of June. As a rule the heavier breeds hatched later than that date are not satisfactory. At least 90% of the pullets in Canada were not laying during November and December of the past Winter, because they were hatched too late.

A Little Sand or Grit First.—When the chicks are removed to their brooding quarters there should be some coarse sand or fine chick grit scattered where they can have free access to it. They should be left until they show positive signs of hunger, which would be between the second and third days after hatching. They may then be given some bread crumbs that have been very slightly moistened with milk; this may be scattered on clean sand or chick rit. If being brooded by a hen, she will see that no food is allowed to lie around, but if in a brooder, that part of the food that the chicks do not pick up in a few minutes should be removed, as nothing in feeding causes so much trouble as leaving food of that nature around until it is sour.

t ian- tff,t etaoin shrdlu lulu lu ininn

Feed for the First Ten or Twelve Days.—The following ration of five feeds given about two hours and a half apart, and continued from the time the chicks are two to three days out of the shell until ten or twelve days of age, may be altered or adapted to suit conditions:—

First feed—Dry crumbs slightly moistened with milk.

Second feed—Finely cracked mixed grains or commercial chick feed.

Third feed—Rolled oats.

Fourth feed—Dry bread crumbs moistened with milk.

Fifth feed—Finely cracked mixed grains.

In addition to the above, give the chicks a little green food, such as grass, lettuce, sprouted oats, etc. Do not have the moistened bread sloppy, but in a crumbly state, and during this period let the chicks on to fresh soil or grass every day if possible.

BUY YOUR WINTER EGGS IN MAY AND JUNE

Good Advice From the Commission of Conservation, Canada.

Eggs laid in April, May and early June keep better than those laid later in the season. If properly treated, they will keep in perfect condition from eight to twelve months. If the egs are to be boiled, the larger end should be pierced with a needle point before putting them in the boiling water.

The eggs, to begin with, must be fresh and clean, not washed clean, but laid clean. If the shell of an egg is not clean, use it at once. If there is a spot of soil on the shell the water glass does not come in contact with the shell and the egg will decay.

A quart of water glass in a five-gallon crock or agate-ware container will suffice for 15 dozen eggs. Clean the crock thoroughly, scald till hot, wipe dry and stand in the sun, if convenient.

Boil 9 quarts of water, allow it to cool thoroughly, then add the water glass and stir well in the crock. Stand the crock in a cool, dry place, and do not move unnecessarily after the eggs are packed. Put the eggs loosely, but carefully, in the solution, leaving a depth of two inches or more over the top layer of eggs. Tie heavy oiled paper over the crock to prevent evaporation. For more than 15 dozen eggs two crocks are preferable to one larger one. After using the water glass once it must be thrown away.

If water glass is too expensive or is unobtainable, add 3 pounds of unslacked lime to 5 gallons of water. After the lime has dissolved and settled, carefully dip off the clear water and pour over the eggs as with water-glass.

Do not pour the water glass or lime water over the eggs till it has thoroughly cooled.

DON'T WASH EGGS

Over 5,000,000 dozen egs are spoiled each year by washing. It doesn't hurt an egg to wash it if it is to be consumed in a short time, but if this egg is put in cold storage, the chances are about one in five that it will spoil. Water removes from the shell a gelatinous covering which helps to keep air and germs out of the inside of the egg. If this covering is removed by water, germs and mold find ready access to the contents and spoil the egg. Only from 4% to 8% of dirty eggs spoil in storage, but from 17% to 22% of washed eggs will spoil.

It is impossible to prevent a certain amount of dirty eggs being gathered, but the quantity can be greatly reduced by using a liberal number of nests, which are kept well sheltered, and an abundance of clean nesting material. Eggs with dirty shells should be used in the home whenever possible. They may frequently be cleaned with a damp rag, but should not be immersed in water.

Shut up or sell the males as soon as the breeding season is over. Their presence does not increase egg production, but lowers it, because 2% to 3% of the females are injured by them.

Who chose the Friction Pulley on your Engine?

90% of the Friction Pulleys sold with Gas Engines are not manufactured by the makers of the engine. When you buy an Engine equipped with Friction Pulley you have your choice of Engine, but someone else choice of Pulley. When buying make certain of satisfaction—choose the pulley yourself—specify, or order direct, Bernard's Double Friction Pulley.

GET THEE BEHIND ME, SATAN!

(By Alice Garland Steele)

Miss Cornelia, in her youth, had willingly renounced "the world, the flesh, and the devil," but even Miss Cornelia had stopped at the last word—it was too awful to be spoken! She had, at the advise of her Sunday School teacher, substituted "Evil One," and as the Evil One was never expected to figure in Miss Cornelia's after life, she very promptly and properly forgot him.

Had there been any doubt of her safety, she had left it behinid her forever when at sixty-five she entered the Old People's Home. This truly was a household of faith, where sainthood was as necessary an adjunct as the three towels, knife, fork anad spoon which one handed over, the very first day to the matron. And yet, strange as it may seem, it was here that Miss Cornelia, turning an unexpected corner, for the first time in her life met the Evil One and fell from grace!

Miss Cornelia had serious blue eyes and lips curved downwards. Her hair, with a stray ringlet or two was demurely parted; her soft, fine skin looked as if some beloved hand forever smoothed out the wrinkles—in other words, Miss Cornelia, who should have been old, looked eternally young.

She was a picture-book old lady. She was pointed out to visitors on Sunday as an example of what the "Home" could do—on voluntary contributions. She was never known to backbite or gossip or find fault with the matron, and she never asked for two helpings of pudding or never mentioned that there were lumps in her bed. To be brief, she conveyed the impression the managers desired—that she was being carried to heaven on "flowery beds of ease."

But Miss Cornelia had to go and meet the Evil One.

It happened on the day of the managers' reception, when the upper halls were closed and the floor below was given over to the matron and the caterer and the florist, and no old lady was allowed down on any pretext whatever. It was like a grown folks' party with the children all sent off to bed! Nevertheless, for days the old ladies had prayed for fair weather, and cleaned out all their bureau drawers on the chance that a stray invited guest would make a five-minutes call, or ask to see the inmates. It is something to be in the same house with a party!

Miss Cornelia, sitting by the window in her neat little room, let her mild eyes wander to the world outside and tried to feel happy. Nancy Huggins was in the rocker with her knitting, and the Widow Brown and Mrs. Parker were on Miss Cornelia's haircloth trunk. The Widow Brown fanned herself with an air of repressed excitement.

"Land of Goshen," she said, "they are fixing up things a lot more than last year! They've got smilax on all the chandiliers and green stuff draping the pictures of the founders and they've ordered the ice cream in figgers."

"And I saw," added Mrs. Parked, "the matron fixing a white ruche in her new black silk. Well, it's consoling to think some folks wouldn't be good-looking with any amount of trimming! I do think she's about the humbliest married person I saw in my life."

Nancy Huggins picked up a dropped stitch. "I don't know as it's wise, Mis' Parker, to say them things. These walls are terrible thin. Besides, a sensible man picks out a humbly woman sometimes, knowing her good points ain't always her nose and teeth."

"Well," sighed the Widow Brown, "I do think those managers are mean as grasshoppers—having their good time all to themselves. I guess you and I, Mis' Parker, could enjoy a lace-paper napkin and a plate of ice cream as well as anybody and I guess we've been to parties enough to know our manners. I hain't always been shut up like this. Why, to my step-datter's wedding we had as much as seven kinds of sandwiches and when I was all rigged out I was 'most as dressy as the bride!" The widow was apt to dwell on the glories of her wornout gowns.

Miss Cornelia looked up, a wistful appeal in her eyes. "What'd you wear?"

"Plum-colored satin. Yes, ma'am, with the front breadth laid in tucks by hand—it was dreadful becomin'."

"Tucks," said Mrs. Parker, "is wasteful, but elegant."

"Elegant? Well, that's what it was. I've got it in the bottom of my box now, but I don't suppose, till I'm dead and gone, I'll have a chance to wear it. I did think of willing it to somebody, but I guess it's a wonman's dooty to look well, even on the Day of Judgment and Samuel always did fancy that plum satin. I rather think he'd live me to wait in it for the Last Trump!"

Miss Cornelia was breathing quickly. Two little red spots had come into her cheeks. "Is it handy?" she said, "I'd love to see that tucked breadth."

The widow got up slowly. "Well," she said, "I'll get it, Cornelia, I'd kind of like you to see it myself."

For the next half hour Miss Cornelia's room was given over to fashion. The plum satin was duly admired and laid carefully full-length on the bed. Mrs. Parker, not to be outdone, brought in a "real lace jabot" that had always been in her husband's family and even Nancy Huggins, who despised the treasures of earth and wore plain linen collars, remembered a carnelian set her mother had worn, and borught it in, reposing in its sabby little velvet case.

Miss Cornelia, stroking a fold of the plum satin, felt her lips quivering a little. "I've never," she said in a faint voice, "been to a party in my life!"

"Good land," cried Mrs. Parker, you poor thing!"

Nancy Huggins resumed her knitting with a humorous twist to her mouth. "A good time," she said evenly, "usually goes to a man's head, and there are some women who can't stand it any better, Cornelia."

Miss Cornelia's cheeks flamed. "I know it's wicked," she said, "but I'd just love to dress up and be stylish for once. I've had to wear plain things all my life, and I've never been to anything livlier than a Sunday School picnic—and in heaven I suppose I'll never have a chance!"

"It's a good thing, Cornelia," said Nancy Huggins decidedly. "Imagine Mrs. Martin Luther goin' to a pink tea, and John Calvin trippin' down the aisle in a swaller-tail coat! I tell you what, Cornelia, the vanities of this world are always deluding us and carryin' us out of our proper circuit, but in heaven the Lord himself looks out for us—we won't be tempted no longer."

Miss Cornelia's voice trembled. "Were you ever tempted, Mis' Huggins?"

Nancy counted four stitches in her knitting. "No, Cornelia—I was born a archangel." And I almost think Miss Cornelia believed it!

Just at that moment the door opened and the second chambermaid thrust her head in. "The matron's been took sick," she announced. "Ain't that awful—and the reception coming off in less than an hour! She's got cramps in her stummick and her eyes is closed up with headache and she wants Mis' Huggins to step down at once and make her a cup of sassafras tea—and you, Mis' Brown, are to help me finish up the dusting."

Nancy Huggins carefully folded away her knitting with a backward nod. "I haven't time, Cornelia, to put away those bangles—just keep an eye to 'em, will you? And Mis' Parker, you better come along with me—she'll need some one to rub her, maybe."

And somehow in a minute they had all fluttered out, and Miss Cornelia, breathless, was alone. Suddenly she was aware that Mrs. Parker had come hurriedly back.

"I was forgetting," she said "I'd left my lace jabot—and I guess I'll just take the widow's dress and lay it on her bed."

"Oh, please don't," said Miss Cornelia. "I mean—" she faltered, "that I feel sort of responsible—andI—I'd like to copy off some of those lace stitches—I thought they'd look so beautiful in my cotton crochet."

Mrs. Parker nodded. "Well, I don't know as I'd trust anybody else with it, Cornelia, but you keep it awhile—I'll come in later and tell you if the matron is better. If they send us up any ice cream I'll take mine with you."

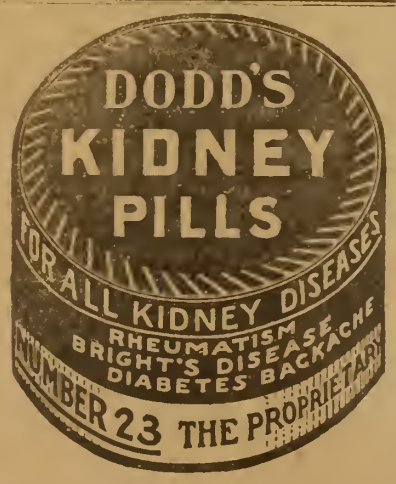
"They won't," said Miss Cornelia, "besides, I'm going to lie down a bit. But you can try my door, Mis' Parker, and if it ain't locked, why just walk right in."

She watched Mrs. Parker go stiffly down the hall and descend the three little steps to the matron's quarters. Then she closed her door and turned the key. She went to the mirror and held the plum satin against her cheek.

"It's really becoming," whispered Miss Cornelia—"and I never was to a party in my life!" And then sudenly she stood very still. There was nobody in the room, but Miss Cornelia dropped the satin dress in a little heap at her feet, and spoke aloud—

"Get thee behind me, Satan."

Alas, Miss Cornelia had met the Evil One. He had been there, strange to say, all the time, peering from behind the folds of the plum-colored dress, luring her with the glitter of Nancy Huggin's gold!



HAD BOILS and PIMPLES ON FACE AND BODY.

Boils and pimples are simply evidences of bad blood that is circulating in the system coming to the surface.

The only way to rid yourself of these painful and unsightly blood diseases is to have your blood purified by Burdock Blood Bitters. It removes every particle of foul material from the blood, and the skin becomes clear and smooth, and free from all eruptions.

Mr. Roy A. Bovay, Trenton, Ont., writes:—"Two years ago I was very much troubled with boils and pimples on my face and body. A friend advised me to take Burdock Blood Bitters. I got three bottles, and before I had finished the third one, my boils and pimples had all disappeared, and my face and body were as clear and as smooth as any baby's could be."

Burdock Blood Bitters has been on the market for over 40 years. You are **not** experimenting when you buy it.

Manufactured only by The T. Milburn Co., Limited, Toronto, Ont.

Now as everybody knows, the Evil One is a foxy old customer and never goes behind anybody of his own accord. You have to grapple with him. You never can get rid of him by reasoning—but Miss Cornelia began to give him her reasons.

'Oh, I know it wouldn't hurt anybody else, and is not what you might call wicked, and I know the matron is sick, but the widow ain't a bit my figure—she's bigger a good deal in the waist. Of course I could tuck it in, but—but I'm not sure—"

You see, the old codger had taken a fancy to this sweet-faced old lady, and he meant to have his way. He showed her just how she could manage!

"But I ought to have a bonnet," murmured Miss Cornelia, "and—and white gloves—" and then she remembered the ones Mis' Peabody had left to her when she died—Miss Cornelia dived into her drawer and got them out. "It does seem," she whispered, "just like Providence—" Miss Cornelia tried her best to ignore the Evil One's hand in it.

Suddenly she slipped off her stuff gown, freshened up her gray curls, and put on the plum satin and the carnelian set, and fastened on the lace jabot, and the bonnet and pinched her cheeks to make them pinker. She was so astonished at the pretty old lady who stared at her from the mirror that she quite lost her head and turned blindly to the door—the hour for the reception had come!

The clock was striking four. Miss Cornelia drew a quick breath, and stepped outisde, locking the door softly behind her. Then she slipped the key into her pocket and tiptoed down the corridor, towards the back stairway. Miss Cornelia knew she must come in, like all the rest of the visitors, by the front door. At the top steps she paused a moment, turning a little faint; her heart was beating in a strange, tumbling way, as if she had given it a shock.

In the hall below she could just see the wooly head of a colored waiter, balancing a tray full of sandwiches. From the matron's quarters, at the other end, she caught faint, sick little moans and Nancy Huggin's quieting voice as she brewed her sassafras tea.

"I'm getting wicked," murmured Miss Cornelia. "I'm glad it's a real bad headache—the kind she has two days at a stretch!"

And then as she descended, she glimpsed the managers, six of them, in Paris gowns, outlined against a room with green biaze doors thrown wide; a room with a soft glimmer of candles and palm decked recesses surrounding a table piled high with glowing roses. Miss Cornelia gasped. Heaven could not be more beautiful! It was worth the shame and fear of being found out, worth everything!

Miss Cornelia slipped out by a back door that opened on a little path which ran through the grounds to the quiet city street. As she walked up to the corner se found a great many stylish people going her way, and a whole row of automobiles. For the sake of the "voluntary contributions" a number of invitations had been sent out and the reckless way in which the "Board" had spent money to make the afternoon one of huge returns was in the nature of a sprat to catch a herring.

As Miss Cornelia passed a great stone house with an iimpressive portier, she stopped an instant, peering at the mysterious dropped curtains. In it lived the wonderful, withered Miss Twitchell—Miss Twitchell, who had come there to live just the April before, who rode out every day in a closed carriage, and hardly let you see her shadow! She was known to keep "family diamonds" in a safe-deposit box, and as far as the world could find out, had never given a dollar to charity in her life!

What sudenly struck Miss Cornelia with a little tremor was the fact that nobody knew Miss Twitchell!

"Nobody has ever seen her close to," murmured Miss Cornelia, and then, as the Evil One whispered a bold suggestion into her ear, she clutched at the iron railing—"My goodness!" she gasped, "I could pertend to be Miss Twitchell myself, and not a soul would ever know the difference! It's—it's Providence!" panted Miss Cornelia—and the Evil One chuckled and waited politely a moment until she got her breath.

Miss Cornelia, with blind inspiration and flushed cheeks, went on. "I am Miss Twitchell," she breathed. "I've been invited to the party, and I'm going—I guess I've got sense enough to remember that and stick to it!" And she added, "It does seem just the Lord's providence that most of the old managers have died off, and the new ones wouldn't be able to tell me from Adam, and—and the matron lying sick on her bed and out of harm's way!" Here the Evil One laughed in his sleeve, but Miss Cornelia could not hear him!

Miss Cornelia, feeling very, very wicked indeed, yet with a joyous thrill at the sheer madness of it, waited at the corner till a very fat person in a gorgeous costume sought admission at the door of the "Home," then she slipped up behind her. The regular doorkeeper, she knew, was not on duty, but she did feel awed as an importanat colored gentleman in a spotless shirtfront demanded her "name please."

Miss Cornelia, very short of breath, pressed forward, and said, "Miss Twitchell, sir" rather indistinctly. "Miss—Twitchell," echoed the colored gentleman clearly, and two of the reception committee forgot their Paris gowns and murmured a sudden little excited welcome. They lifted, as it were, the plum satin between them straight over the threshold, and placed it importantly inside, with a murmured word to a "new manager" in a very straight gown, who ushered Miss Cor-

Simple Herbs Cure Serious Troubles

MANY of the diseases of womanhood may be prevented with care. Unusual excitement—mental or physical—disturbs the delicate balance of woman's sensitive nerves, and upsets her whole system. At the first indication of nervousness or any irregularity, take

Dr. Wilson's HERBINE BITTERS

It's safe and certain—purely vegetable—regulates kidneys and bowels—overcomes headaches, indigestion, stomach trouble—purifies the blood—tones up and invigorates mind and body.

I KNOW A WOMAN'S SUFFERINGS

I am a woman.

What I have suffered is a far better guide than any MAN'S experience gained secondhand.

I know your need for sympathy and health.

And the treatment that gave me health and strength, new interest in life, I want to pass on to you, that you, too, may enjoy the priceless boon of health.

Are you unhappy, unfit for your duties? Write aud tell me how you feel and I will send you ten days' FREE trial of a home treatment to meet your individual needs, together with references to women in Canada who have passed through your troubles and regained health; or you can secure this FREE treatment for your daughter, sister or mother.

If you suffer from pain in the head, back, or bowels, feeling of weight aud dragging down sensations, falling or displacement of internal organs, bladder irritation with frequent urination, obstinate constipation or piles, pain in the sides regularly or irregularly, bloating, dyspepsia, extreme nervousness, depressed spirits, melancholy, desire to cry, fear of something evil about to happen, creepiug feeling up the spine, palpitation, hot flashes, weariuess, sallow complexion, with dark circles under the eyes, paiu in the left breast or a general feeling that life is not worth living, I invite you to send to-day for my complete ten days' treatment entirely free and postpaid, to prove to yourself that these ailments can be easily and surely overcome at your owu home, without the expense of hospital treatment, or the dangers of an operation. Women everywhere are escaping the surgeon's knife by knowing of my simple method of home treatment, and when you have been benefited, my sister, I shall only ask you to pass the good word along to some other sufferer. My home treatment is for all,—young or old.

Read My FREE Offer:

To Mothers of Daughters, I will explain a simple home treatment which speedily and effectually dispels green-sickness (chlorosis), irregularities, headaches and lassitude in young women, and restores them to plumpness and health. Tell me if you are worried about your daughter. Remember it costs you nothing to give my method of home treatment a complete ten day~ trial, and if you wish to continue, it costs only a few cents a week to do so, and it does not interfere with one's daily work. Is health worth asking for? Write for the free treatment suited to your needs, and I will send it in plain wrapper by return mail. Cut out this offer, mark the places that tell your feelings, and return to me. Write and ask for the free treatment to-day, as you may not see this offer again. Address:

MRS. M. SUMMERS, Box 309 - - Windsor, Ontario

Daughter, SOUR STOMACH

Mother, FLOATING SPECKS BEFORE EYES

BOTH CURED BY

MILBURN'S LAXA-LIVER PILLS.

They stimulate the sluggish liver, clean the coated tongue, sweeten the breath, clean away all waste and poisonous matter from the system, and prevent as well as cure all sickness arising from a disordered condition of the stomach, liver and bowels.

Mrs. Joseph H. Thericau, Saulnerville, N.S., writes:—"I was troubled with a sour stomach, and took five vials of Milburn's Laxa-Liver Pills, and they cured me.

My mother also used them for floating specks before the eyes. They cured her also after having taken four vials. We both highly recommend them to all sufferers from .liver troubles."

Milburn's Laxa-Liver Pills are 25c. per vial at all dealers or mailed direct on receipt of price by The T. Milburn Co., Limited, Toronto, Ont.

nelia in gracious silence down the palm-decked room.

From a far corner a violin sounded dreamily, and in a dream herself, Miss Cornelia found a soft-gloved hand pressing hers, while a very young voice said: "How perfectly dear of you to come!"

Miss Cornelia looked dumbly upward. My, but it was a sweet face! "Are—are you a manager?" she said.

"Oh, yes, indeed, very much a manager—Teddy says they couldn't run it without me, though I've only been on the Board a month! Teddy, you konw is my husband. They are such dear old things—the inmates, I mean—I do hope I can interest you in the work. I'm not a bit businesslike, they just call me the manager with the soft heart! Have you met our president?"

Still holding Miss Cornelia's hand she led her to a stately person with gold lorgnette, and made a halting, but very earnes presentation.

"Beg pardon?" said the stately person. "I didn't get your name?"

"Miss Twitchell," said Miss Cornelia after a sharp pause—"I live in the house across the way."

It was wonderful the effeet it had on her hearers. They seemed to draw breath and then bend forward in a delighted effusiveness. And as the group enlarged, Miss Cornelia found herself the center of a rapt little circle, that hung on her words.

"Yes," noded Miss Cornelia, growing suddenly bold. "I didn't exactly get an invitation, but I'm interested in old people, because, you see, I am old too."

"No invitation? Why, dear me, I sent you one myself!" The soft-hearted manager was flushing deeply. "You see, they were all a little bit afraid of you, but I knew you had such a lot of—I mean that there are such lovely things one can do if—" she bit her lip and her cheeks grew a lovely crimson, but Miss Cornelia steadiliy smiled.

"Well," said Miss Cornelia, "it must have gone astray—but I know what you mean—I do think the reason I've not given much to charity is because it is charity. Now for instance, in a place like this—the inmates ought to have a carriage ride once in a while—the only kind they ever get is driving to their own funerals!"

The stately person lifted her lorgnette. "Dear me," she said, "how oddly you put it."

The soft-hearted manager broke in quickly. "Oh, do give us some more of your ideas—I—I think you are quite right about the carriage rides—I'm going to send them out in my automobile often, now that I realize they'd like it—we are trying to do what we can for them, and it is beautiful work"

"It is a beautiful work," agreed Miss Cornelia loftily, "but it doesn't go far enough."

"Far eough—" echoed the stately person, "it goes just as far as we can possibly make it. It costs inconceivably."

Miss Cornelia's lips curved; her serious eyes grew more serious; she saw with delight that little group of Paris gowns were hovering about her, drinking in her words—she felt she could go as far as she liked—and they would believe her! She thought up some beautiful brazen lies that would make them all sit up and take notice, and she didn't care two pins that the Evil One was egging her on!

"Of course it costs," said Miss Cornelia solemnly—"but I'll tell you what—if there were certain things, improvements made, I don't know but what I'd promise to give something myself—say five thousand dollars."

The soft-hearted manager gasped. Several of the faces expressed a rigid joy. Here then was the herring coming straight into their nets! They had only to put out their hands and take it!

"But," said Miss Cornelia steadily, "there'd have to be chanages. There'd have to be a eup of tea served to every inmate at five o'clock with buttered toast, regularly, and ice cream for Sunday dinner and not so much baby-food. They haven't all got false teeth and it would do some of them good to chew a little. And there'd have to be a ride, now and then, in the park, and nice, soft mattresses, not hard as corn-shucks—and on Saturday, if they wanted, to go to a moving-picture show, everybody goes to moving-picture hows nowadays, and it seems to me they ought to have a chance at it too." Miss Cornelia paused for breath.

"Can you think," said the stately person, with ominous calm, "of anything more."

"Yes," said Miss Cornelia serenely, "stamps and—pocket-money. If you have a mind to do all this, well—I think I'd add another thousand to the five." Miss Cornelia was going at a mental gallop. Though she didn't realize it, she had much the same sensations, when she staked that final thousand, of a person betting on a race eourse. She had her nerve with her and she didn't care.

The stately person was fanning vigorously. "Pocket-money," she murmured, "why it's outrageous, pocket-money—if she weren't Miss Twitchell—"

A manager in blue suddenly appeared on the outer edge of the circle. She had steel-blue eyes and her smile held a certain hard authority. "Who is that odd person?" she asked trenchantly, but the soft-hearted manager gripped her hand—

"Hush—she's promised us six thousand dollars—it's that wealthy Miss Twitchell from across the street!"

"Miss Twitchell? Why she's nothing of the kind—" her voice came forcefully out of a vast indignation—"I beg your pardon—but would you give me your name?"

Miss Cornelia grew very faint, her eyes were strangely bright, like a robin's, when a cat is by—"My name," she said, "is Twitchell."

There was a sharp pause. The violin, in the corner, was playing "The Rosary"—but to Miss Cornelia it no longer seemed like heaven—she even thought she heard hushed, diabolical laughter. The Evil One seemed to stand, with the manager in blue, on the edge of the crowd!

"Aud you live," said the manager in blue, "in the stone house across the way?" her voice was saturated with courtesy.

"Why, yes when I'm home, but I go most summers to Europe—I live sometimes here and sometimes there—" Miss Cornelia was fluttering now, a tiny bit, and her knees felt as if they might fail her without due warning.

"She seems," murmured the stately person auadibly, "very familiar—ahem—with our institution."

"I once knew—an old lady," said Miss Cornelia bravely, "who stayed here till she died. They all do die—if

"I Believe They Have Cured Me"

WHAT NEWTON P. SMITH SAYS OF DODD'S KIDNEY PILLS.

He Had Previously Tried Doctor's Medicine, Plasters and Liniments for His Sore Back, Without Getting Permanent Results.

Parker's Ridge York Co., N. B., June 8th.—(Special)—After suffering for years from pain in the back, Newton P. Smith, a highly respected citizen of this place, believes that at last he has found a permanent cure through the use of Dodd's Kidney Pills. Asked to make a statement, Mr. Smith said:—

"I suffered for a number of years with pain in my back. At times I was unable to work. After taking doctor's medicine and using plasters and liniments with but temporary results, I decided to try Dodd's Kidney Pills, which I believe have cured me."

All through oYrk County you find people who give credit to Dodd's Kidney Pills for a renewed lease of health. They have been tried for all forms of kidney disease, including rheumatism, dropsy, Bright's disease, lumbago, heart disease and diabetes, as well as the milder forms of kidney trouble. Their papularity all over the country i sa tribute to the splendid results obtained. If you haven't used them, ask your neighbors about them.

you give them time enough—"

"Oh, please don't," whispered the soft-hearted manager, "it seems so rude to question her that way—" aloud she said, "Won't you come and have an ice, Miss Twitchell, or a frappe or something? It's really very nice."

Miss Cornelia moved hurriedly. "Thank you, my dear," she said faintly, "Yes, I'll have an ice." She felt herself drawn apart, into one of the palm-decked recesses, but she knew that curious and doubting eyes were following her. She suddenly, as she sank into a camp-chair, felt very tired and worn.

The soft-hearted manager fluttered over her with a gentle word or two about the heat and the crowd, while Miss Cornelia gulped down minute portions of the ice. Suddenly something, a longing to be herself, made her say very quickly in a frightened little whisper—

"My dear, I—I can't cheat you any longer—I'm just a wicked old woman, and not Miss Twitchell at all!

"Hush," murmured the soft-hearted manager, "go on eating your ice, dear."

"I'm not Miss Twitchell at all," persisted Miss Cornelia—her voice was broken a little, and her face had gone gray, 'I'm just one of the inmates, and I've never been to a party in my life and I wanted—wanted to come!"

"I know," murmured the soft-hearter manager, "I saw you in chapel on Sunday—just at first I couldn't remember, but afterward I did, and I'm so sorry. Don't you think, dear, after you've finished, you'd better slip quietly out?"

Miss Cornelia put by her plate with a trembling hand.

"Oh, no," said the manager, "wait and finish it, please— it's so nice."

But Miss Cornelia shook her head. 'No, I'd rather go—and—and—thank you for being so kind to a wicked old body like me—but I just couldn't go on deceiving you, I had to tell you the truth!"

(Continued next issue.)

Spanking Doesn't Cure!

Don't think children can be cured of bed-wetting by spanking them. The trouble is constitutional, the child cannot help it. I will send **FREE** to any mother my successful home treatment, with full instructions. If your children trouble you in this way, send no money, but write me to-day. My treatmeut is highly recommended to adults troubled with urine difficulties by day or night. Address

DATE CUSTARD PIE

1 Cupful Finely Chopped Dates
½ Teaspoonful Salt
2 Cupfuls Milk
4 Tablespoonfuls Butter
4 Tablespoonfuls Flour
3 Tabelspoonfuls Sugar
2 Eggs

Mix the salt with the flour and stir into the butter, which has been melted. Add the milk an stir over a moderately hot fire until it comes to the boiling point. Add the dates and the sugar. Now move the vessel to the back of the stove and let the mixture simmer until the dates have softened. When slightly cooled, add the beaten yolks of the eggs and pour into a lined pie-tin after the pastry has been allowed to harden. Use the whites for the meringue, adding after the custard has set.

PRUNE CUSTARD PIE

1 Cupful Seeded Prunes
3 Tablespoonfuls Sugar
1 Tablespoonful Corn-starch
1 Salt-spoonful Soda
2 Eggs
1 Cupful Sour Milk
Pinch of Salt

Stir the sugar and salt into the beaten yolks. Add the milk to the corn-starch into which the soda has been sifted, taking care that it does not form lumps. Add the two mixtures together and stir in the prunes, which must be chopped finely so that they will mix thoroughly. Pour this over the pastry and bake. Use the whites for meringue, flavoring with lemon-juice.

DAMSON PRESERVE CUSTARD PIE

1 Qt. Damson Preserves
3 Eggs
1 Tablespoonful Corn-starch.
1 Cupful Butter or Butter Substitute

Drain the juice from the preserves and remove the stones. Mix the beaten egg yolks with the damsons, add the butter, and then the corn-starch to give it body when cooked. Bake and add the meringue in the usual way. This recipe makes two pies.

Minard's Liniment Co., Limited.

I was very sick with Quinsy and thought I would strangle. I used MINARD'S LINIMENT and it cured me at once. I am never without it now.

Yours gratefully,
MRS. C. D. PRINCE.
Nauwigewauk, Oct. 21st.

Sunshine Furnace Efficiency

McClary straight walled firepot—no ashes to absorb heat.

The test of furnace efficiency is the volume of heat it conserves for **actual use**, from the heat generated in **burning** your **fuel.**

There is a fixed volume of heat in every kind of fuel, whether it is wood, soft coal or anthracite.

The business of your furnace is to extract **all** the heat, which **all** furnaces do—and to conserve the **maximum** of it for use—which the **Sunshine** furnace **does.**

The Sunshine semi-steel firepot is built with **straight** walls—not sloping to form and hold a non-conducting deposit of ashes. A very important point in furnace efficiency.

The grates of the Sunshine furnace are equal in area to the firepot, so that fresh oxygen—without which proper combustion is impossible—flows to every part of the fire all the time.

All air passages are exactly proportioned so that neither too much nor too little air passes over the radiator—there can be no superheated air, nor any under heated air, sent to the rooms above.

The doors, drafts and dampers are machined to fit snugly and to exclude heat-wasting air currents from the outside.

Usual sloping wall firepot. Blanket of ashes absorbing heat.

Engineering Service Free.

McClary's own heating engineers are at your service when you buy a Sunshine Furnace, to give you free expert advice on your home-heating requirements. Write to the nearest McClary Branch and ask for particulars about this service. A booklet, "Comfort in the Home," makes clear all the things you want to know about furnaces and it is sent free on request.

Runners May be Prevented in hose that are too tight over the knees by splitting the back seam down halfway and neatly inserting a V-shaped gore taken from the back of a discarded hose.

Root Vegetables, such as turnips and carrots, that have been withered need not be thrown away. Revive them by slicing off the ends and laying them in cold water. In a few hours their natural freshness will be restored.

An Excellent Table Pad, which may be used in place of a flannel or asbestos silence cloth, may be made by sewing together eighteen or twenty sheets of newspaper and covering them with heavy muslin.

Bean Sacks Make Splendid Roller Towels for the kitchen, and your grocer will be glad to sell them to you at a small cost.

Your Lettuce Will Not Wilt and therefore have to be discarded if you will wash it thoroughly and keep it in an earthen jar tightly covered.

If Your Hot-Water Bag is past mending do not discard it, but cut off the top, open the bag out flat and cover it with a pretty colored linen. Fold into the desired shape and use as a wash-cloth, toothbrush, soap and sponge holder when travelling.

Less Fuel Will be Required and less food wasted if food is served as much as possible in individual ramekins and custard cups. This is particularly true of baked meat molds or timbales, custards and other individual desserts.

Correspondent Answered

"What does one raise when he sows wild oats?" asks a correspondent. Well, we know one young man who raised cheques. And his crop led to a close crop in the State's prison.

When Children's Ribbed Stockings are hopelessly worn out, unravel the remaining parts of the legs, wind the cotton or wool on a spool and use for darning other stockings.

A Small Bookrack may be made from a good sized wooden box, by adding shelves and papering it inside with a plain paper to blend with the walls of the room. The outside may be varnished or covered with cretonne.

Old Suspenders, Washed and Ironed, make splendid inside belts for skirts. Since they are narrow, lap two edges together and stitch them on the machine. They do not get flimsy after washing, as regular belting does.

HOW SHALL WE DRESS IN WAR TIME

The question of how to dress in war time confronts every woman who wants to do her bit—and who doesn't? Was there ever a time when the women of the world played a greater part! The world today has an army of women workers, women from every walk of life, working side by side in the hospitals and reconstruction work abroad, in the Red Cross, the Y. M. C. A., and in war relief work of all kinds here in America. Their thoughts and their hearts are not intent on gaiety or even on their own interests, but on how they can help in this great fight— a fight that has become theirs, since it takes those they love.

Naturally, then, there is a seriousness which compels simplicity even in clothes; lines are straighter—to save wool for soldiers; and dresses are fewer—to save pennies for the sufferers.

The hopeful person in times of stress is she who retains her poise—her sanity. And to this problem of dress, as to all others, let us bring sanity. Let us dress with moderation in the clothes of the new season; let us choose those which are suited to the work we are doing. If we have a war job let us have a war job dress—a simple tailored frock or suit; if we have a social duty, again let us be suitably gowned in a softer dress. Let us buy what we need sanely and wisely for ourselves and our children, in proportion to our incomes, remembering that in buying wisely we are sustaining not only the clothing inudstries but the great allied interests as well. Let us keep these industries going, but let us abstain from needles luxuries, when by so doing we may add our mite of thrift and help to our cause. And our mite, be it only the War Saving Stamp of the youngest girl who reads this, is a real and vital help to our Government. And, above all, be cheerful. Look your best. Do your best. Don't let yourself down; don't let others down. Keep yourself and your home in readiness for the flying visit of its absent soldier. It is in such ways as these that we do our part.

Mothers of young children have a distinct duty just now. Feed a growing child as he should be fed, and you have helped make a good citizen. We sall need good citizens after the war as greatly as we do now. Every child has a right to a useful body and mind. These he cannot have without the right food at the right time. How serious it is when mothers through careIessness or from ignoranace, permanently injure a child's chance in the world!

It has been stated that the most important period in one's life is the first five years. Where is that time spent? In the home. Why is that period most important? Because habits are formed then that remaini with one throughout life. Not least among these early habits are the food habits acquired. How inconsistently some mothers are regardinig the wants of the child at this time. A mother often spends much tiime and thought in the selection and making of the child's wardrobe, but puts any kind of food in his stomach and boasts that her baby can eat "anything." Instead of indicating great precocity in her child, she is only exposing her ignorance. One should as quickly put French heels and corsets on a child as to put "grown-up foods" in his stomach.

Do not force a child to eat. If he is not hungry, do not try to tempt his appetite by offering sweets when simple food is required.

lym18sGetaoi csmflu mfwyp bgqj bk

Teach him to chew his food thoroughly.

Keep the child happy at meals. "Laugh and grow fat" applies to children as well as adults.

Do not give children highly seasoned food. This is avoided by taking out the child's portion before seasoning the dish for the family.

It is far better to give the child his meal apart from the family when you may take time to train him in good eating habits.

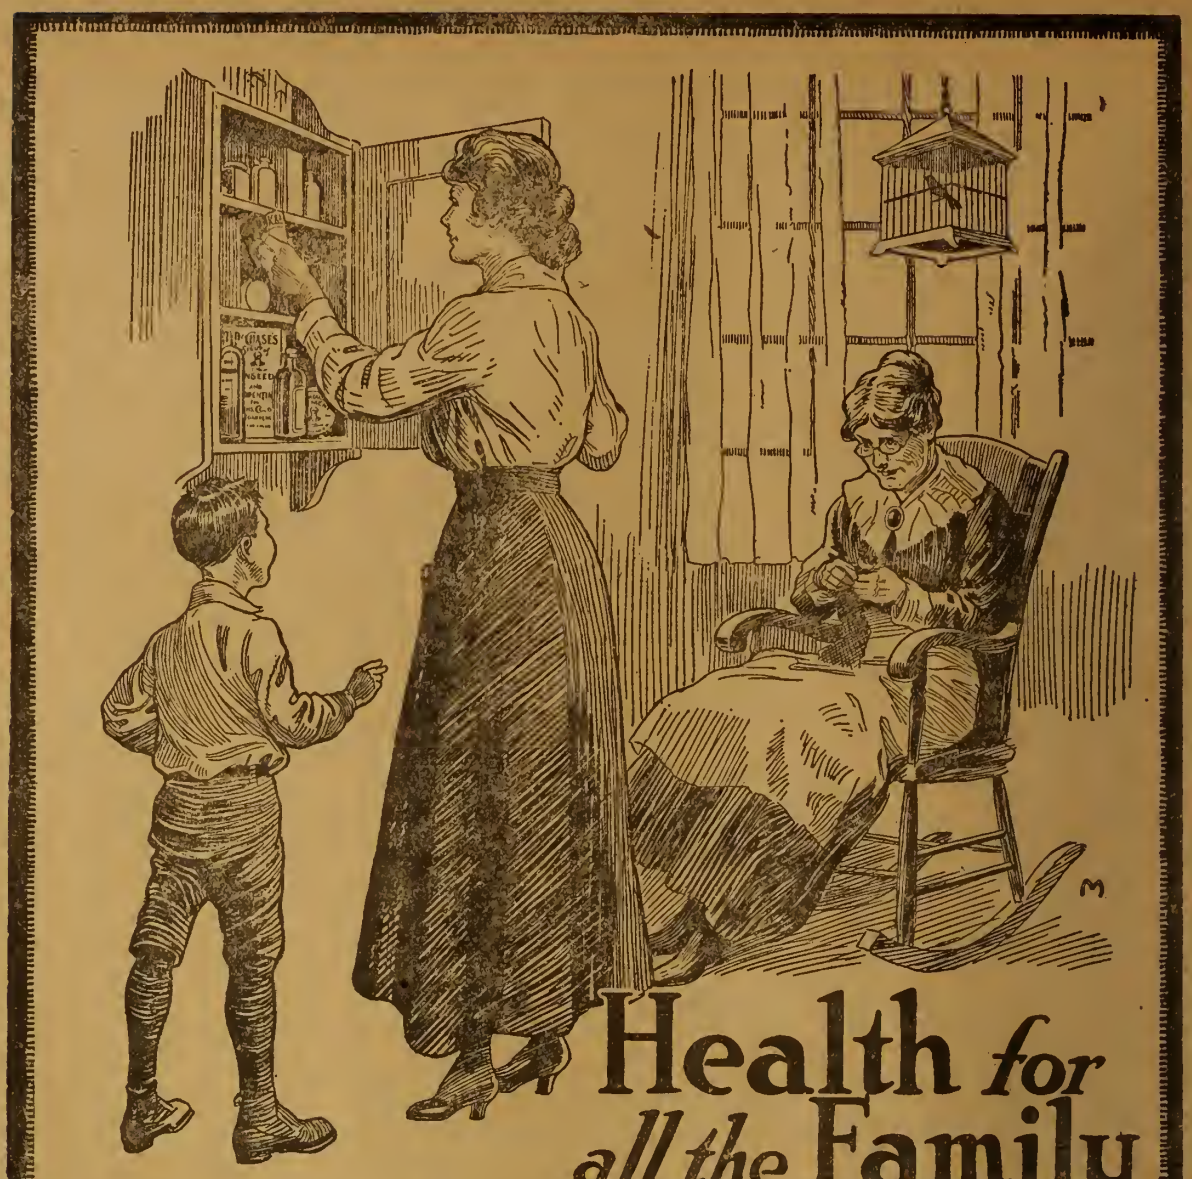
The value of milk can not be overestimated; use of oatmeal, hominy, and cornmeal, as the chief source of energy, is always wise; little or no meat is necessary until a child is six years old; little or no sugar is needed, if the child has the proper fruits.

An evening of fun, which can be turned into a money-maker as well, is the little party decsribed in this column. In these days when half the world is at war, there are so many worthy appeals which must be met that this asmusing little party should offer some welcome suggestions. The Red Cross needs our help in every possible way to tmeet the many demands for the sick and wounded—among them perhaps some of our own boys who have gone across to fight our battles for us!

Try an Alphabet Party and see what a fat check you can send to the needy ones. Word your invitations as follows:

"Here is quite the newest yet—
Mr .and Mrs. Alphabet
Will entertain on————eve
It will be fun, you may believe.
Two cents a letter for your names
Is all it costs to joi the games
And feed in an alphebitical way.
We need the money, you the fun,
We'll all be sad if you stay away.
At eight and thirty, 'twil be begun.

Collect your admision fees at the door and give each guest, or group of guests if there are a great many, a sheet of paper bearing a single letter of the alphabet. Within a limited time each must construct a four stanza verse, each line of which begins with the letter drawn. This may be made a source of great amusement by suggesting topics of local interest. Bind all the verses together into a booklet



Health for all the Family

MODERN, artificial methods of life make it absolutely necessary to use medicines occasionally to ensure the regular and healthful action of the liver, kidneys and bowels.

In the great majority of homes Dr. Chase's Kidney-Liver Pills are recognized as the most satisfactory regulating medicine for all the members of the family.

This medicine is not in any sense a cure-all, but its use occasionally, as required, ensures the activity of the liver, kidneys and bowels, the cleansing of the system, and the purifying of the blood.

For this reason you can depend on Dr. Chase's Kidney-Liver Pills to prevent and cure constipation, torpid liver, indigestion, kidney derangements and resulting painful ailments, such as backache, rheumatism and lumbago.

Dr. Chase's Kidney-Liver Pills are so universally used that you can obtain them at any store where medicines are sold.

Dr. Chase's Kidney-Liver Pills

One pill a dose, 25 cents a box, all dealers or Edmanson, Bates & Co., Ltd., Toronto.
Do not be talked into accepting a substitute. Imitations only disappoint. 11

at the close of the contest, and give them as a prize to the most sucessful poet.

SCALES SHOULD BE A PART OF KITCHEN EQUIPMENT

Every household kitchen should be provided with a set of small scales for weighing small articles purchased by the pound. We are so in the habit of assuming that all weights are correct that this little precaution against unfair weights and unavoidble mistakes is omitted. The honest merchant will welcome your checking your dealings with him, and will apreciate the co-operation. A small balance of the platform type can be had for $2.00 or a little less and will be of great value to the household.

HOW TO CLEAN SENSIBLY

It is always possible to let cleaning go, but no housekeeper wants a disorderly house. To reduce labor and still keep order, let go the idea that anything but surface cleaning needs to be done regdlarly. Scraps and litter and surface dust should be removed daily, but other cleaning, such as carpet-shaking, paint-scrubbing, closet-cleaning, window-cleaning and all such work as women are wont to plan to do once a week or once a month or once ayear, is very often done at a stated time as a matter of course—whether there is a real need for it or whether there is not.

Just now it is housecleaning time, and many a cellar and attic will be overhauled because it needs it, and many others will be overhauled just because it is house-cleaning time.

To my mind there should be no such thing as a housecleaning. There should be no appointed time for the taking up of rugs and carpets and the overhauling of closets and the scrubbing of paints. To turn a house topsy-turvy to clean shows bad management. Such things should and can be done one at a time as they are needed, without exhausting the housewife or her family.

EPSOM SALTS FOR TURKEY POULTS

I have been feeding Epsom salts to poultry and it seems to me one of the best medicines for poultry I have ever used. It is much easier to prevent disease among poultry than it is to cure it, and I have used the salts as a preventative. It has proven very valuable to me.

I wish to tell of my experience in curing young turkeys of bowel trouble, which is usually called cholera. For several years we had been raising turkeys, sometimes with success, but generally our luck was varied. Every year we would lose some with bowel trouble. Last summer our turkeys seemed to do well for a time and then they began to die. Many of them were so sick they would not eat. With the help of members of the family we went to the turkey lot and tried the last thing towards saving them. We mixed salts with water and wheat bran, and put this down the throats of the turkeys so they were compelled to swallow it. Some of them got, perhaps, nearly a teaspoonful of the salts. This was continued for five or six days on the entire flock. All except two that were too near dead, began to grow stronger. Gradually they improved and in about ten days they began to eat, but they became afraid of their "feeders" and we were compelled to put the salts in their feed. They soon began to grow fast and by October they were as large as the old turkeys.

Although the poults required lots of care and the treatment was lots of bother, yet I believe it was time well spent. Chickens can be cured of bowel trouble in the same way as I have cured chicks that would surely have died without the treatment. The doses for chicks should not be as large as we gave the poults. A teaspoonful will make a dose for three chickens. I am sure the salts will keep them in good condition. JOHN E. FISHER.

SHERWIN-WILLIAMS PAINTS & VARNISHES

COVER THE EARTH

"COMMONWEALTH" BARN RED

The Paint for Barns, Roofs, Fences, Etc.

S-W COMMONWEALTH BARN RED is a bright, rich Red, that works easily, covers well and dries with a fine, smooth, durable finish. Put up in convenient sized cans, all full Imperial Measure. Why not try it this year to protect your barn against the weather?

You have a heavy investment in farm machinery, implements, wagons, etc. Increase their life and usefulness by protecting them against rust and decay, by using *SHERWIN-WILLIAMS WAGON AND IMPLEMENT PAINT*. The longer they last the less they cost.

It is economy to use *S-W BUGGY PAINT* on your buggies and carriages, and *S-W AUTO ENAMEL* on your car. They give entire satisfaction and are easy to apply.

Color schemes and suggestions for any part of your building furnished by expert decorators, free upon application and without any obligation.

Send for our book:—"The A.B.C. of Home Painting" written by a practical painter, telling how to paint, varnish or enamel every surface in and around your home.

TREES INJURED BY MICE OR RABBITS CAN BE HEALED

(Continued from page 553)

serted, should soon unite with the stock and then carry the sap to the top of the tree.

One of the most satisfactory methods of utilizing the badly girdled tree is to cut it off close to the ground and insert a scion of some good variety. This graft should grow at least three feet in height the first season and make a nice young tree.

A young tree may sometimes be saved when the girdling is well above the graft by cutting the tree back so as to remove all of the injured part. Under such conditions young trees will usually make new growth and the strongest shoot may be selected to form a new trunk and top life for the tree. This method is not usually very satisfactory if the injury occurs more than two years after the tree has been planted.

DOUBLE DAILY SERVICE TO PRINCE EDWARD ISLAND

ALL RAIL SHORT ROUTE

Tormentine—Borden and Car Ferry

With the Summer Time Table in effect June 2nd, there will be a double daily service between the Mainland and Prince Edward Island. Passengers by the Maritime Express from Montreal and the morning expresses from St. John and Halifax will be able to arrive at Charlottetown 7.05 p.m., Summerside, 6.05 p.m., and Tignish 9.35 p.m. By the Ocean Limited from Montreal, the Boston express via St. John, passengers will arrive Summerside at 11.00 p. m. and Charlottetown 11.20 p.m. From the Island by leaving Summerside at 6.30 and Charlottetown at 6.00 a. m., passengers will connect with the Ocean Limited for Montreal, the express for Boston and the Maritime Express for Halifax. By leaving Tignish at 9.30 a.m., Souris 6.45 a.m., Charlottetown 12.50 noon, and Summerside, 1.30 p.m. passengers will connect with the Maritime Express for Montreal.

CONTROL OF SWARMING

(Experimental Farms Note)

One of the greatest problems in beekeeping today is the control of swarming. tI is natural for a strong colony of bees to swarm in early summer when honey is coming in, but the breaking up of the colony cuts down the honey yield; while watching for and hiving swarms takes a great deal o fthe beekeeper's time, and the swarm may escape notice and fly away.

The methods of controlling swarming that have been tested at the Central Experimental Farm, Ottawa, fall under three heads.

(1) General measures. Partly shading the apiary; providing a large entrance with deep space between combs and floor; giving plenty of room in the brood chamber and supers; and young queens. These measures, while valuable, have been found insufficient in themselves to prevent the bees from raising queens in preparation for swarming.

(2) Manipulations to prevent more than one swarm. The queen's wings are clipped, preferably during fruit-bloom, and when a prime swarm issues and is still in the air, the queen is picked up from the ground and placed in a cage, and the hive is removed to a new stand. A new hive containing the caged queen is then placed on the old stand to receive the returning swarm, the queen being liberated later. The field bees join the swarm, leaving the parent hive so much weakened that it is not likely to swarm again. To make certain of this, however, the parent hive may be merely turned around and not removed to the distant stand until five days later. This method of swarm control necessitates immediate attention when the swarm issues, but, as the manipulations are simple, they can often be carried out by the home folks should the beekeeper be away.

(3) Manipulations to prevent swarming altogether. At the time of writing, none of the manipulations that have been tried has succeeded except the cutting out of all queen-cells every seven or eight days, and this failed during a heavy honey flow from clover at Ottawa in 1916 when the bees raised queens from worker larvae, and swarms issued before the queen-cells were capped over. It has, however, been found possible to prevent swarming in out-apiaries, forty miles north of Ottawa, by this means, although it entailed weekly visits from the middle of May until the middle of August, and much time was spent in examining each colony.

Experiments in the control of swarming are being continued, especially along the following lines, which seem the most promising:—

(1) Testing systems of raising brood to the super. Many of these will delay swarming under some conditions.

(2) Finding means by which the brood chamber may be easily examined without lifting off the supers. A hive in which the brood combs are in a rack that can be drawn out sideways is being tried.

(3) Endeavouring to breed a strain that will not swarm, of which the preliminary step is to find out if the non-swarming character shown by some queens is inherited. A queen showing this character was found to retain in the following year.

ADVANTAGE OF STRAIGHT COMBS

Beekeeping in New Brunswick is in its infancy—here and there we have a man who has read up on the subject, and putting theory into practice has succeeded, and has been able to gain practical knowledge to convince him that there is money in the business, if properly attended to.

There seems to be one point about which there appears to be many confused ideas and that is, the hive question. Some people buy modern hives and pay big prices for them without considering why these hives were designed. They hive their swarms, in some cases without comb foundation, and the bees arrange matters to their own sweet will. Modern hives, without modern methods, are no better than the old box hive—sometimes not as good. Langstroth designed the first good working frame hive—his idea being to have straight combs, every one of which could b etaken from the hive and returned with the least amount of disturbance. This hive has been adopted by all sucessful beekeepers. There are many modifications of the first type of Langstroth, but practically every frame hive in use today is patterned after the Langstroth principle. It is considered a crime to keep bees in hives in Ontario, and bee inspectors have the authority to warn the beekeepers that unless their bees are placed in frame hives within a reasonable length of time they will be destroyed. This law is rendered necessary because of the seriousness of the diseae situation in that Province.

Modern hives with frames properly wired and filled with foundation are a satisfaction to the beekeeper and a joy to the inspector.

Every large producer of honey has his frames wired and embedded in the foundation, or he could not put them through the extractor without a large amount of breakage. The wires keep the foundation from warping when the bees are placed in the hive, and thus he has straight combs tbat can be taken from the hives and replaced without mashed bees or leaking honey.

When queens become crowded for laying space swarming is bound to follow—unless we can remove some of these combs and place empty combe ni their place. This is impossible in any hive with crooked or immovable combs.

The Massey-Harris Trademark

Gives a feeling of security when Harvest Days draw nigh.

IF your Binder bears the MASSEY-HARRIS TRADE-MARK you can rest assured that your Harvesting operations will be completed ON TIME and to your entire satisfaction.

Harvest Days are busy days—every minute counts, and a delay in the completion of the cutting may mean serious loss. You can't afford to take chances—it's better to be sure than sorry.

The Massey-Harris Binder

is known the World over for its Reliability.

This is no idle statement but is backed up by the experience of thousands of farmers all over the world, many of whom have Massey-Harris Binders which have been in use for from 10 to 20 years and are still giving the best of satisfaction.

If you have never used one, ask your neighbor who has and profit by his experience.

Massey-Harris Co., Limited

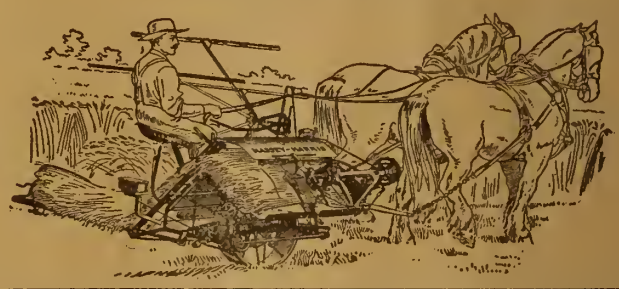
—Agencies Everywhere—



In the spring beekeepers nearly always have some colonies light in stores while others have more than they require. With straight combs this matter can be regulated by giving a comb of honey from the rich colony to the starving one. In swarming time some beekeepers make a practice of placing a frame of unsealed brood in the centre of the hive before hiving the swarm. This is considered a sure method of holding the swarm and well worthy of a trial by anyone.

As long as we keep bees in hives the frames of which cannot be handled we are working in the dark and can never expect success by any such haphazard methods.

ALSIKE AND WHITE CLOVER AS HONEY PLANTS

(Experimental Farms Note)

Farmers know the value of the two perennial clovers, alsike and white Dutch clover, for hay and pasture, but it is not always remembered that a large bonus may be obtained from them in the form of honey. They produce more honey in Canada than all other plants put together, and this honey is of the highest quality.

Production of clover honey is greatest in the farming lands of Eastern Canada. Almost the whole region south of the Ottawa River is excellent. The St. Lawrence River Valley is almost as good. The valleys of the St. John, and other rivers in New Brunswick, marsh hay lannds in Nova Scotia and the rich farming lands of Prince Edward Island and around Lake St. John, Que., are very good too. In the clay belt of Northern Ontario, notably around Haileybury and Dryden, these clovers grow in immense quantity and luxuriance, and some years produce heavy honey crops. While alsike as a commercial honey plant has reached its highest development in the Eastern Provinces, white clover does well in a large part of Manitoba and British Columbia.

The cultivation of clover on suitable lands as a combined farm and honey crop is ercommended as follows:—

(1) Growing alsike with timothy for hay. Alsike is better for this purpose than red clover because the latter is of practically no value for honey production and is beginning to spoil by the time the alsike and timothy are ready to cut. Alsike will grow on certain types of soil, for instance, ill-drained land, better than red clover.

(2) Growing alsike for seed. An abundance of honey bees increases the yield of seed per acre; and leaving the plant to produce seed lengthens the honey ow.

(3) Sowing white clover in grass mixtures intended for pasture. On favourable lands the white clover will keep spreading, improving the pasture both for cattle and bees. Grazing, if not too close, will not seriously curtail honey production, and it lengthens the honey-flow.

The honey-flow from clover lasts three to five weeks, beginning, according to latitude, between mid-June and mid-July. Good management of

the bees, to build them up strong in time for the honey-flow and keep them from swarming, is necessary. There is no better food for bees in winter than clover honey.

CANADIAN BANKERS' COMPETITION FOR BOYS AND GIRLS

In this competition, the Canadian Bankers' Association, acting in co-operation with the Dominion Department of Agriculture, Live Stock Branch, offers cash prizes to boys and girls who exhibit pigs or calves at their local fair, and who comply with all the rules governing the competition.

In districts in which there are School fairs the prizes shall be offered at the School fair unless in the opinion of the Managers of the Banks in the district, (to be ascertained by the bank earliest established in the district) the prizes should preferably be offered at the Fall Fair.

Rules

1. Only boys and girls who have not attained their 17th birthday before the opening day of the show are eligible to compete in the Canadian Bankers' Competition.
2. No entry fee will be charged.
3. No exhibitor shall be allowed to make more than one entry in a class.
4. Not more than one member of a family shall be allowed to compete in a class.
5. An exhibitor who wins a cash prize at one fair shall not be allowed to compete in the same class at another fair.
6. Calves and pigs entered for competition must have been born on or after March 15th, 1918, and must be the property of the exhibitor or the exhibitor's parent or guardian.
7. Grade bull calves, and grade boars, are not eligible to compete, and entries for same must not be accepted.
8. Exhibitors must feed and care for the animals they exhibit for at least six weeks.
9. An application form and a certificate form are attached hereto.

(a) The application form must be properly filled out and fyled with the manager of a local branch bank at least three weeks before the date of the fair.

(b) The certificate must be filled out and signed by the parent or guardian of the exhibitor, and fyled with the Secretary of the Fair not later than the day of the competition. If, however, an exhibitor fails to present his certificates on the day of the competition, he shall be allowed to compete, but any prize he may win shall be with held until a properly filled and signed certificate is produced, and said certificate must be forthcoming within forty-eight hours afte rthe holding of the competition, otherwise his prize money shall be forfeited.

10. In case the winner of a prize is subsequently disqualified, each exhibitor below him shall be moved up one place.

CLASS I.

(Grade bull calves must not be shown)
CALF, PURE BRED OR GRADE.
Prizes:—1st, $5.00; 2nd, $4.00; 3rd, $3.00; 4th, $2.00; 6th, $1.00; 6th, reserve.

CLASS II.

(Grade boar pigs must not be shown).
TWO PIGS, PURE BRED OR GRADE.
Prizes:—1st, $5.00; 2nd, $4.00; 3rd, $3.00; 4th, $2.00; 5th, $1.00; 6th, reserve.

OX WARBLES

In a recent issue of The Monthly Bulletin of the Ohio Experiment Station, the following statements are made with reference to the control of the ox warble:

"The only effective combative measure thus far known is the squeezing out of grubs from the backs of the infested animals in the early spring months. The eggs are laid during the summer mainly on the hair of the legs of cattle. Young maggots are found in the gullet during September—February, after which they appear under the hide on the back.

"These grubs may be located on the back by small swellings. Each lump is perforated by a small hole through which the grub emerges in the spring and early summer. After dropping to the ground the grub passes through the pupal, or resting stage, and in3 to 6 weeks the adult fly escapes from the pupal case and later the female lays her eggs on cattle.

"Killing all such grubs as soon as they are 'rips' and can be easily squeezed out of the back between the thumbs will control this cattle pest. All the grubs, however, must be killed in each herd before a community will be free.

"Hides are reduced in value from 1 to 2 cents a pound by the presence of warble flies, acocrding to estimates reported by hide buyers. Flesh must sometimes be discarded as unfit for food; milk yields are freueqntly lessened, and cattle in general are annoyed by the pests. Removing and destroying the grubs will tend toi reduce their numbers each year."

Are You Working for the Machine *or* Is the Machine Working for You?

No one wants to be bossed by a bell, or chased by a speedometer. Fixed-feed separators are hard taskmasters, unless cream waste means nothing to you. How much better it is to have your separator skim clean at any speed—working *for* you, not against you. Only one separator does this—the Sharples suction-feed. It skims equally clean at all speeds, averaging a saving of 10 lbs. of butter per cow yearly over any other separator. Every time you turn a Sharples you are saving the butterfat that will help win the war.

SHARPLES SUCTION-FEED CREAM SEPARATOR

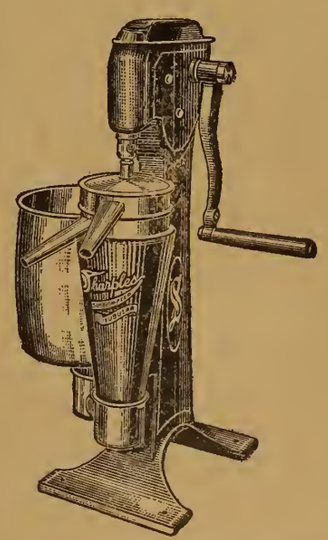
—the *only* separator that will skim clean at widely-varying speeds

—the *only* separator that gives cream of unchanging thickness—all speeds

—the *only* separator that will skim your milk quicker when you turn faster

—the *only* separator with just one piece in bowl—no discs, easiest to clean

—the *only* separator with knee-low supply tank and once-a-month oiling



Remember—Sharples is the *only* separator that automatically prevents cream losses, and doesn't rely on human nature. Write for catalog today to nearest office, addressing Dept. 79

HANDLING COW AT CALVING TIME

Much of the future usefulness of the dairy cow depends on the care given at calving time. If she is turned out in cold stormy weather, gets ice water to drink, and is improperly fed, the chances ar ethat she will prove a disappointment to her owner.

Acow should he dry from six to eight weeks. If milked right up to the time of freshening she will have a weak calf, and her pow of milk will not be as lrage as it should be. She should be fed liberally during her resting period to enable her to put on flesh and nourish the unborn calf.

The week before due to freshen our cows are fed lightly of feeds of a laxative nature—silage, alfalfa or clover hay and bran. This loosening up of the system will go a long way in preventing milk fever, garget and retention of afterbirth. I believe this is far better than the practice some farmers make of feeding patent medicine mixtures of unknown merit to cure all ills the cow is subject to during this time.

SHEEP AND SWINE

Sell the brogen-mouthed ewes and any others that have not proved good producers, and get the ewe flock in good condition before breeding begins.

Coughs and pneumonia from dusty beds ma yincidentally be prevented if louse-infested beds are oiled Breathing dust may cause death from pneumonia and certainly renders hogs less resistant to cholera.

Next to goats sheep are the greatest scavengers of weeds and waste vegetation known to the American farmer. Df 500 varieties of weeds and grass, 482 were eaten readily by sheep in a test at the Minnesota station.

One point that many farmers overlook in handling sheep is that they should have a change of range every few years. After sheep have run on one pasture for a period, they will do better if transferred to new range.

The reason for sows eating their pigs is largely a matter of feeding. To avoid this trouble give the sows a good growing ration without too much corn or other fattening food. Give them roots or potatoes occasionally and plenty of exercise.

You May Dream Dreams

and see Visions, but to make your Dreams come true—and your Visions materialize—generally means having a little capital to start with.

The way to get capital is to save a part of what you now earn.

Decide, now, to let us help you to save. Interest paid every six months.

Butter Parchment at Farmer Office

ONLY HEIFER THAT IS WELL DEVELOPED WILL DO HER BEST AS A COW

The writer wants to confess right here that he has grown some cows that are too small today, that are limited in productive power on that account, because he did not know how to feed a calf, and because he did not appreciate the importance of keeping the young heifers growing every day until they were fully developed. Today the younger cows on our little farm are larger than the others and our young heifers are much more promising because wihle we have a great deal to learn, we have discovered some things that help.

First. We are feeding more new milk to the young calf than we formerly did. It takes courage to feed whole milk to a calf when butter-fat is above fifty cents. We may modify it with skim-milk to the above proportions. In my own practice I discontinue most of the whole milk by the time the calf is four weeks old, substituting it with skim-milk. But I continue to allow the calf two pounds of whole milk per day for two or three weeks longer.

The danger of over-feeding must always be guarded against. More calves are compelled to drink too much skim-milk than are fed too little. The amount they are able to take with profit depends upon their weight and upon their individuality..

The matters of grain and roughage are very important in the development of the calf. Calves should begin to eat a little of grain by the time they are three weeks old, but only a little. The practice of putting a small amount of grain in the bottom of the pail after the calf has finished the milk is not objectionable, but if handled right the animal will soon learn to eat dry grain from a box and this is a more convenient way of feeding. Great care should be taken not to give the calf too much grain at the start. If we do we shall disturb the digestive process, the calf will get a set back, will refuse to eat the grain and we shall have a lot of unnecessary bother. There is not the least trouble in the world in teaching a calf to eat anything it ought to eat if we proceed slowly enough. In time, when the calf is accustomed to grain, it may be given all it will eat up clean without any danger of trouble.

The matter of roughage is as important as that of grain. Here to we should begin carefully and proceed slowly. A very little clover or alfalfa at first, or even mixed hay will answer. I would only give the calf a little. What the animal wastes does it no good. By the time the calf is four weeks old it may begin to eat ensilage. Indeed, I have fed ensilage to calves as the only roughage and had them do very well. With hay at present high prices, and with silos filled with the abundance of corn that was worth little for anything else, I should not feed much hay to calves this winter. As soon as I had determined the amount of grain the calves would clean up with a relish I would put that grain on the ensilage exactly as for the older animals, always taking care not to feed them a greater amount than they will consume in from half to three quarters of an hour. The practice of keeping feed constantly before young animals is bad. The ideal feeder will know how much the animals will consume promptly. He will feed them to this limit and will not be in the least disturbed to see their mangers perfectly cleaned until the next feeding period arrives. A friend of mine, one of the most successful dairy men I know, says he wants his cattle to be anxious enough for their feed so that they will try to jump into the silage car as it passes in front of them, and yet several of those heifers are making two pounds of fat per day during this cold weather. Nobody ever saw a bovine animal with that kind of an appetite if it were in the hands of a careless feeder.

The Power Behind Your Farm Work

Power is a dominant feature on your farm today. Equip yourself with an efficient power plant and your results are half assured.

A Fairbanks-Morse "Z" Engine

does the work of several men better and more economically.

150,000 farmers are daily demonstrating that the "Z" is the greatest engine value ever produced.

Get acquainted with it and save money. You will find it economical and easy to operate.

For pumping, lighting, sawing, cutting the feed —the "Z" Engine fills every want.

Skim Milk as a Frame Builder

There is a tendency not to continue the skim-milk long enough in the life of the calf. We have been getting splendid results from skim-milk without knowing why. Personally I used to think of it merely as a source of protein, but I did not know that the

For Factory-Farm or Dwelling

Amazon Roofing

A handsome, durable, economical roof that can be laid by anybody without previous experience or special skill. Just unroll Amazon and nail it on the roof.

It is not too heavy to handle easily. It is very pliable, easy to cut and fit, and very tough. Nails, cement and caps are supplied free.

Amazon is handsome enough for a dwelling, durable enough for a factory, inexpensive enough for farm buildings.

THE BARRETT CO., LIMITED

Ad. No. 4.

protein in the milk was two and a half times as available as the protein in grains, and yet such is the case. I used to think of the value of the milk sugar but did not fully understand its availability but the thing we all overlooked in the past, I am sure, is its mineral value. No animal can be developed normally without a proper proportion of mineral in the ration. To deprive a young animal of milk is to limit the ultimate size. If we are constructing a building we first erect the frame. We cannot build a dairy animal without a frame, and to make the frame takes mineral in plenty, and we cannot build it anywhere so easily or so cheaply as in skim-milk. We should continue it until the animal is six months old at least, and preferably for a longer timie.

It is hard to over-estimate the value of good pasture for young dairy animals. Last fall I turned a bunch of heifers into some very fine clover and it was interesting to watch them grow. Yes, good pasture is all right, nothing in the world is better for dairy animals of any age, but it is scarce and where it is not good we must supplement with something else. It will not do to let these young animals stop growing. A little grain once or twice each day, some oats and peas in their season, cornstalks a little later on, a patch of alfalfa close by, all these will help. Perhaps the most convenient thing of all is the summer silo but the all important matter is in some way to keep these young animals growing.

The dairy heifer at from two or two and a half years of age should be a well developed animal. If she has been neglected she may be partially developed after her work as a cow has begun but she will never reach the extent of production of which she might otherwise have been capable. The writer has a cow of very strong milking tendencies. When a calf she was unfortunate in having more than a calf's sare of indigestion. When she freshened the first time she was under size. She soon gave thirty-two pounds of milk per day, but she could not consume feed enough to continue at that rate of production so she borrowed from her little body until her production diminished to a point where she could eat enough to keep even. She is naturally a good cow but I am losing anywhere from $10 to $25 a year by not having assisted that animal to grow a strong body that was able to do the work for which her inheritance has fitted her.

And now may we say a word in closing, about feeding the heifer during her first period of lactation. Here again it is up to the man. Truly, it takes a wise man to develop a dairy animal, to know just how and when to feed, to know what to feed and how much, to watch the cow from day to day and feed her as an individual and not simply as a member of the herd. These are requisites of a good dairy man but to acquire them takes application and experience. No heifer is fully developed at two years. The lighter breeds may begin milking then with profit, but the Holsteins should have a little more time. During the first milking period two objects should be kept constantly in view. First, the further development of the animal, and second the production of milk in paying quantities. We must not overfeed for we do not want to impair digestion and limiit development, and we must not under-feed because if we do the animal will fall off in flesh, then in vitality and we shall be very sure to fail in our purpose.—W. F. TAYLOR.

Oats is a good poultry food. There is some risk, however, in feeding whole oats. The hulls may cause impacted crops and death. The best way to feed oats is to crush them, sift the hulls out and feed in the mash.

The shell of an egg is porous and filth on the shell will enter and poison the contents. For this reason dirty eggs should be cleaned as soon as gathered. A little baking soda on a damp cloth will assist in cleaning the eggs. As little water as possible should be used, as water opens the pores of the shell, causing rapid evaporation of its contents, and permitting the entrance of germ life, which causes decay.

It is never a paying policy to keep the large, slow-moving hens and the small, active hens in the same flock. They require different methods of feeding and attention.

Hens should be kept in a state of contentment. The attendant should handle them gently. A fright that sends the hens to the tree tops will check egg production. The dog should be kept out of the poultry yard.

McLAUGHLIN VALVE-IN-HEAD MOTOR CARS

"Motorwise" Buyers are using McLaughlin Cars

McLAUGHLIN cars are more and more coming into popular favor among Motor wise men who make a minute study of real motor car value.

Now that motor cars are such a factor in business, men look for that particular make of car representing highest value for the amount involved. McLaughlin cars give uninterrupted service due to their efficiency.

Men who buy McLaughlin cars are assured of real service—the kind of service which many companies are unable to give.

McLaughlin cars are made in Canada at the large McLaughlin factories in Oshawa. They are distributed through 12 directly owned McLaughlin branches, and over 400 dealers. Branches and dealers keep repair parts and expert mechanics, assuring prompt and efficient service when it is needed.

MONTREAL

The Provision Market

Montreal, June 6.—A decidedly weak feeling developed in the Toronto market for live hogs yesterday and prices dropped $1.50 per 100 lbs. with sales at $18.75 per 100 lbs. weighed off cars, and at $18.50 fed and watered. There was no further change in the condition of the Winnipeg market, but the tone was easy at $17.75 for selects weighed off cars. In sympathy with the above the local market was weaker today and prices scored a further decline of 50c per 100 lbs. The offerings were small, but ample to meet all immediate requirements and sales of selected lots were made at $19.50 to $20 per 100 lbs. weighed off cars. The market for dressed hogs was quiet and easy and lower prices are expected in the near future. The demand was limited and only for small lots to fill actual wants. Sales of abattoir fresh-killed stock in a wholesale jobbing way were made at $29 to $29.50 per 100 lbs.

There was no actual change in the condition of the market for smoked or cured meats, but the feeling was easy and the prospects are that if prices for hogs go any lower there will be a re-adjustment of prices in the near future. The demand continues steady for domestic consumption and a fair amount of business was done in a wholesale jobbing way with sales of 8 to 10 lb. hams at 38c per lb., 12 to 15 lbs. at 34c to 35c, and heavier weights at 32c to 33c, while breakfast bacon sold at 41c to 42c, Windsor selected bacon at 44c to 45c, and Windsor boneless bacon at 46c. The tone of the market for barrelled pork is also easy with only a small trade passing in a wholesale jobbing way in Canadian clear fat back pork at $62; Canadian clear plate pork at $61, and Canadian sort cut back pork at $59 per barrel.

The tone of the market for lard remains about steady with a fair demand for supplies and sales of pure leaf grades in a wholesale jobbing way were made at 32c to 33c per lb. in 20 lb. wood pails, and compound lard at 27c per lb.

Mill Feed and Rolled Oats

Montreal, June 6.—A steady business continues to be done in most lines of millfeed, and the market is moderately active, with no change in prices to note. Sales of pure grain moullie were made at $72; bran at $35, shorts at $40, and other grades of feed at from 5$1 to $68 per ton, including bags, delivered to the trade. The demand for oat product continues rather quiet and prices are unchanged with car lots of rolled oats quoted at $4.85 to $5 per bag of 90 lbs. ex track, and in broken lots at $5.10 to $5.15 per bag, delivered to the trade. There was no change in cornmeal, for which the demand is steady, and a fair business was done in broken lots of Golden grade at $6.25 to $6.40, and bolted at $4.50 to $4.75 per bag delivered to the trade.

The Baled Hay Market

Montreal, June 6.—The condition of the market for baled hay was unchanged . The receipts at present are small, but stocks on spot are large, and especially so of the low grades, for which there is practically no demand just now, while the trade in the higher grades is only moderate. There was no further change in prices, but the tone of the market is easy, with car lots of No. 2 hay selling at $15.50, No. 3 hay at $13.50 to $14, and clover hay quoted at $6 to $9 per ton ex track.

Country Produce

Montreal, June 6.—A somewhat unsettled and easy feeling prevails in the egg situation, but there is no actual change in prices to note as yet. Storing at the lower level of prices now ruling in the country is reported to be more active than previously on the part of some firms. With the limitation of profits on eggs, the trade generally is taking no chance an dthis may lead to lower market later on when the real warm weather sets in. One of the redeeming features of the present situation is the continued heavy consumption and another one is the fact that stocks of cold storage eggs on spot are smaller than at this period a year ago. The domestic trade was fairly active today there being a steady demand for supplies for immediate requirements at unchanged prices. The receipts today were 905 cases, as compare dwith 1,186 for the same day last week and 1,727 for the corresponding date a year ago.

We quote wholesale jobbing prices as follows:
Selected new laid eggs....44c to 45c
New laid stock.....00c to 42c

What CP Means to the Farmer

C.P. means Paint of only one quality—the best. It contains only the purest Oils, the best Lead and Zinc, mixed in scientifically correct proportions, and ground to the finest degree.

The Farmer knows, by careful comparison of cost per gallon and length of time on the house, that C. P., CANADA PAINT, is unquestionably the most Economical and the Best Paint for anyone to use.

"HOMESTEAD LIQUID RED" is the paint for Barns and Silos. One gallon covers 300 square feet, two coats. Ask the C.P. agent in your town for any information required.

Write us for your copy of our new paint book, "What, When and How To Paint". Sent free upon request.

Happy Farmer Tractor handling 3 bottom 14 inch plows backsetting Timothy Sod

Thirty-One Cents an Acre!

At Brandon the Happy Farmer demonstrated its ability to plow an acre in 45 minutes at a cost of only 31 cents worth of coal oil! Compare this with the cost of plowing an acre with your best team, with feed at high prices, and men's extra time to be counted in. Will it not pay you to use the

Happy Farmer Tractor

Model A—8-16 Horsepower. Model B—12-24 Horsepower.

Here is the ultimate tractor for efficiency and economy combined! It is famous for its simplicity—few parts to get out of order. Any intelligent farm lad can run it. It is heavy enough for the hardest plowing test and for heavy hauling—light enough to use with the drill. And it will go anywhere; it will plow right up to the fence with no unfinished corners. It will turn in its own space and not mire in soft spots.

Model B's engine is not just "adapted" to coal oil. It is designed *specially* for kerosene. It burns it perfectly—all of it—with no smoke nuisance and no carbon trouble. Model B will not only pull the plow and the binder, getting your work done early in critical times, but it will deliver 24 horsepower for all kinds of belt work at low up-keep cost.

If you prefer a lower power tractor, Model A supplies the need.

Write us for full particulars about price, delivery terms, etc. Literature free on request.

No. 1 stock.....00c to 40c
No. 2 stock.....00c to 38c

The situation with regard to poultry is very firm in this country. Storage stocks are getting into very small compass, with some varieties already sold up. The demand continues good, and all live and fresh killed receipts are picked up at full prices on arrival. Fowl and cocks form the bulk of receipts and a few broilers and spring ducks are arriving. The demand for poultry has been unprecedented, and dealers report they expect all storage stocks to be cleand up by August 1st. Supplies of live poultry on the United States markets were lighter, and the active demand in many instances strengthened prices. Frozen poultry is reported to be moving satisfactorily. Much deterioration is apparent in arrivals of ice-packed, and these have moved at low and irregular prices.

There continues to be a steady demand for maple sugar for export to the United States, and further sales were made at 23c to 23½c per lb. f.o.b. country points, while on spot sales in a jobbing way were made at 24c to 24½c.

80 Years of Knowing How

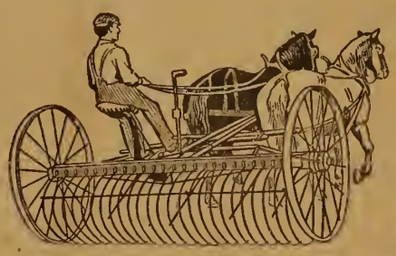
Tried, Proven and Popular Everywhere

THE FROST & WOOD MOWER CUTS ANY CROP

What you must have from your mower is dependable service—it must be ready to cut any kind of a crop, no matter how heavy or tangled—and it must be ready for work when the hay is ready to cut. Just use a little judgment in the selection of your mower—don't be afraid to be influenced by the example of thousands of successful farmers—make your choice a Frost & Wood and you will always have that comfortable feeling that your hay crop is safe, if a handy, easy-to-drive, light draft, dependable mower has anything to do with it.

The superior mechanical features of the Frost & Wood mower, the "internal drive gear," the special cutter bar, the improved knife guards, the modern roller-bearings, the always-cutting knives, carbon-steel construction, etc., are too numerous to deal with here. Get our "Hay Making Equipment" circular.

Frost & Wood "Tiger" Automatic Dump Rake



An all-steel implement, weather-proof and ready for the hardest kind of work year after year. The axle is immensely strong, is always revolving, so sagging in the centre is unknown with this Rake. The wheels are high, giving ample clearance; the teeth are the highest quality steel, carefully tempered and tested so they last for years. The Automatic Dump feature is worked by a small foot trip, the teeth coming up quickly and easily to dump the windrow. Light draft, good work and many years of it, are built into this Rake.

Ask the nearest Frost & Wood agent, or write our nearest branch for a copy of the Frost & Wood Folder, "Efficient Equipment Makes Hay-making a Pleasure."

Advertise in the FARMER

Mahone Bay, N. S., 1918.

Mr. R. U. A. Landsman,
Prosper Hill.

Dear sir:—

Answering your valued inquiry for information re potato spraying outfit, beg to say that the pump is all brass, for the reason that the liquid will rust the inside of anay pump having an iron air chamber or iron pipes touching the spray. This rust, breaking loose, pumps into nozzle and clogs them. The piston of the pump is packed with a special fibre packing, made in such a way that it can be kept tight for years and new packings cost but little. The relief valve at the base of the air charmber permits pumping the liquid back into the cask, thus with the agitator and the returned liquid the mixture is quickly brought to a uniform strength. This valve will also drain the pump when you are through spraying.

The four row potato spraying attachment has a strongly built iron frame. The mixture is conducted to the nozzles through hose and brass pipes. The spray boom can be folded for passing through a gateway, or packing away when not in use. The nozzles can be adjusted for width of row and instantly for height and angle of spray. Four nozzles follow the tops of the rows and six intermediate nozzles spray the sides of the vines. The stop cock is just at the hand of the opeartor so that the spray can be shut off instantly. This apparatus can be attached to any cart or wagon, and one man can operate the sprayer as well as drive. This attachment can be used with any pump of sufficient capcity. These outfits have been known to run for several seasons without the nozzle once clogging. The straining hopper with brass wire cloth tacked in on an angle cleans the liquid when it is upt into the cask. The buttons permit of the quick removal of the pump from the cask.

The tree spraying attachment of hose, bamboo rod, double nozzle, etc., makes this sprayer into an orchard outfit. With these fine features and many others you see they are well named the "Perfect" spray pumps.

Trusting to be favored with your valued order.

Yours very truly,
R. B. WESTHAVER.

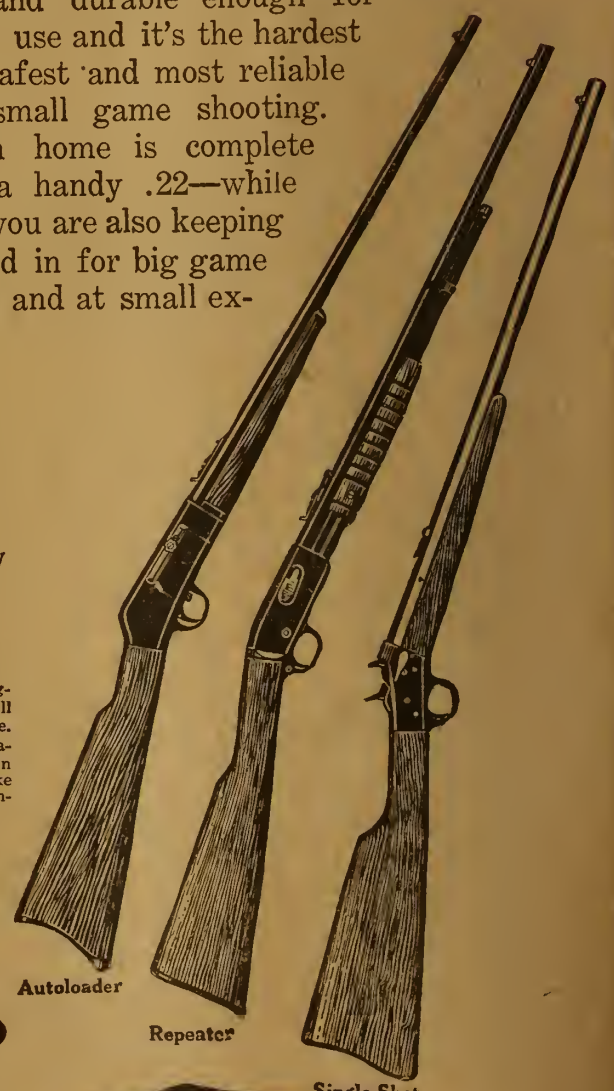
HEROLD'S FARMS, Fruitland, Ont.
Dept. L Niagara District,

REMINGTON UMC
TRADE MARK

Make him a good shot—

Teach your boy to shoot with a real manly arm—a Remington U.M.C. .22 and get him U.M.C. ammunition. See him become self-reliant, manly—rightly proud of his shooting, as his scores improve.

The Remington U.M.C. .22 Rifle is rugged and durable enough for the boy's use and it's the hardest hitting, safest and most reliable for all small game shooting. No farm home is complete without a handy .22—while using it you are also keeping your hand in for big game shooting, and at small expense.



Autoloader

Repeater

Single Shot

Three Remington U.M.C. .22's—all are beauties

The Remington .22's are distinguished for clean, graceful lines, safety features, facility of take-down and accuracy of fire. Here they are:

Rem. U.M.C. Autoloader

The king of all 22's. Gives you 15 fast, smashing shots as quick as you want to press the trigger. Not the slightest disturbance of the aim. Weighs only 5½ lbs. The solid breech—a feature of all Remington U.M.C. Arms—is a wall of steel between the shooter's face and the firing chamber. Hammerless, simple and very accurate. Nothing to touch *this* shooting.

Remington U.M.C. Repeater

A beautiful weapon—operates by a smooth-working slide action; with practice you can stream the 15 shots with lightning speed. Shoots .22 short, .22 long, and .22 long rifle, mixed if you like, and they never clog or jam. Hammerless—nothing projecting to catch in clothing, etc. Side ejection. Made of highest grade steel—accurate, rugged, perfectly finished.

—and the Single Shot

An inexpensive but strongly built weapon that will give years of good service. Solid breech. Safety features, very acccurate in shooting because we make it as carefully as our highest price weapons.

Remington U.M.C.—means the best in arms and ammunition

For a big game rifle—see the wonderful Remington 5-shot Autoloader or the 6-shot Repeater. Cartridges—we make over 450 kinds. In shot guns, the Remington "Pump Gun" knows no equal. In shot shells—try the Wetproof, steel-lined Arrow and Nitro Club—very fast. New Club is the best black powder shell.

June Air In January

Most any furnace will produce a dry heat--the kind used to dry lumber in a kiln.

But that kind of heat will ruin the health of your family and destroy your furniture.

What month is the balmiest, healthiest, sweetest, most delightful of all the year?

June of course.

The Sunshine Furnace has been designed, developed and perfected to give to your home in January the same quality of air that you breathe out of doors in June.

The Sunshine Furnace by warming fresh air and charging it with the necessary exact degree of moisture, not only warms but ventilates your home with pure, soft, healthful air every moment of the day.

Above the fuel door of the Sunshine Furnace is a water pan designed with scientific exactness to vaporize into the warm air the precise quantity of moisture necessary to the health and comfort of your family.

In the Sunshine heated home there are no dry, hacking throats, no burning or wrinkling skins, no dust or gas—only pure, humid, balmy, healthful warm air.

Engineering Service Free McClary's own heating engineers are at your service when you buy a Sunshine Furnace, to give you free expert advice on your home-heating requirements. Write to the nearest McClary Branch and ask for particulars about this service. A booklet, "Comfort in the Home," makes clear all the things you want to know about furnaces, and it is sent free on request.

STOMACH WORMS IN SHEEP

The stomach worm is the parasite which does the most damage in the American stocks but it may be successfully combated if the flock receives proper care and management. Many cases of "bad luck" with sheep are due to a combination of improper feeding and stomach worms. We all know that when an animal is not in a well-nourished condition it is more susecptible to attacks made by parasites and diseases, hence, we see why the man who does not keep his sheep in a thrifty condition is not going to be overly successful.

It is easy to detect a member of the flock that is infested with stomach worms. The unfortunate animal looks weak and dull, lets its head hang, hangs back from the rest of the flock, becomes thin in flesh, and oftentimes scours. Its fleece becomes harsh and dry and hte skin becomes pale.

Stomach worms cause the principal oss in the case of lambs. They are found in the fourth or true stomach. These worms are of a reddish color and are from ½ to one inche in length and are about as thick as a hair. Older sheep are not free from these pests an dusally are harbors of these worms. Full grown sheep may be heavily infested and yet show no marked symptoms.

The worms laden with microscopic eggs pass out in the feces from the older sheep and are scattered about the pasture. If the temperature is below 40 degrees the eggs will remain dormant, but will retain their vitality ofr two or three months. If the tem perature is above 40 degrees, the eggs hatch out in from a few hours to two weeks.

The young worm feeds upon the organic matter in the manure until nearly 1-30th inch in length. It then crawls up on a blade of grass, if there is sufficient moisture, and the temperature is above 40 degrees. At this stage the worms will stand freezing and drying for some time, and have been known to live six months at a temperature above 70 degrees. It is safe to say that a pasture wihch has had no sheep on it for ayear will be practically free from the parasites. At the Ohio experiment station a group of lambs fed all summer in a barn were kept free from parasites, while another lot turned out to pasture was badly infested. This, together with other similar results, proves that lambs get these parasites on pasture.

Methods of Prevention

As the lambs become infested from the older sheep and infected pastures, it is essential that great care be taken to remove the source of infection. Thus it is essential that we rotate our pastures as much as possible, and so arrange it that the lambs do not run on pastures where it is possible that the young worms have reached the infectious stage. If possible the sheep should be changed onto a fresh pasture every two or htree weeks during the months of June, July, August and September. Annual forag ecrops, such as rape, are especially desirable to afford this rotation of pastures.

There are numerous worm powders and medicated salts upon the market and some of these have merit. Some flock masters think that feeding tobacco helps prevent parasites. Some keep before their flock a mixture of wood ashes and salt sprinkled over with turpentine. If the lambs have been so handled that they are free from worms when weaned from the ewes and put on fresh pasture, there is not much danger of infection ,especially if pure water is provided for them to drink.

Among the most common remedies are gasoline, turpentine, benzine and coal tar cresote. Lambs that are to be treated should be separated from the remainder of the flock the evening before and placed in a building or dry lot where they will not receive anything to eat or drink. This precaution should be taken in order that the stomachs will be empty when the drench is given.

Size of Dose for Lambs

Practically the same amount of gasoline, benzine or turpentine is recommended. Following is dose for one lamb:

5 ounces cow's milk.
1 tablespoonful gasoline.
1 tablespoonful raw linseed oil.

For older sheep the amount of gasoline may be increased to 1½ tablespoonfuls, but the amount of milk and linseed oil would be the same The dose should be mixed separately for each lamb and administered on three successive mornings. A small-necked bottle is best for drenching, and great care should be exercised to prevent the liquid from reaching the lungs.

Experiments have shown that there is less danger of reaching the lungs and more certainty of reaching the fouth tomach when the sheep is kept in a standing position with nose elevated no higher than the eyes.

After giving these remedies we should not forget the fact that it is absolutelys esential that we provide pasture free from infection for the young lambs and get rid of infected sheep and pasture as rapidly as possible.—Prof. H. H. Kildee, Minnesota College of Agriculture.

Every Farmer Needs a Ford

THE Motor Car is a greater convenience to the average farmer than the telephone, the rural mail or even the grain binder.

The binder which is considered as a very useful implement is rarely used more than a few days during the entire year. The rest of the time it stands idle, taking up space, while the automobile is available for use throughout all seasons, and both day and night.

It is ever ready to run down the lane to the back field or the pasture with a parcel or a message, or take you and your family to town for shopping purposes—or on an errand to the neighbors.

The motor car is called upon whenever anything is wanted in a hurry. It is the most useful implement or convenience for the farm. It helps you conserve your energies and time for productive work and enables you and your family to accomplish more with less energy. You surely feel the need of a Ford. Why not order one today?

FILE VS. GRIND STONE

One can't sharpen a hoe on a grindstone, awkward to hold and trembles. I always file. Fasten the shank in a vise, blade up, file on the inside and the ends as well. Always keep the corners square, you can then hook out a weed from a hill or plant without stooping. There is a pleasure in having a tool work easily. Your axe must balance and so should your hoe. Select one that is light, thin and well tempered, with the proper "hang" and nicely balanced. If you hoe all day file in the morning and at noon. It's only a few minutes if you take the "stitch in time." If you haven't a steel screw and vise go right away and get one. I would as soon think of chopping witha dull axe (so the wood would burn better) as to hoe with a dull hoe so as to pull the weeds out. We can speed up a little when every tool is sharp. We must to produce what we have to—"our bit."

If you are going to sell your surplus cockerels at six months of age, don't caponize, for the cockerels will make greater growth to that age and at cheaper cost. Beyond six months of age capons will do better.—[Prof. Lester E. Card.

FINANCIAL ASSISTANCE TO PROSPECTIVE SHEEP BREEDERS

Editor the Maritime Farmer:

The war has created an unusual demand for wool and meats and there is every prospect for a contnuance during many years of firm prices on all livestock and their products. This Province is eminently adapted for sheep raising and the result of the grading of wool this year proves beyond a doubt that the quality is very high.

The essential foods for sheep are grown within the Province and instead of having about 100,000 sheep there should at least be 500,000. The time is at hand when we must put forth an effort to produce more of our requirements or at least have more animal products to sell. We have the climate, food, also market for the finished product, but we lack the stock.

At the last session of the New Brunswick Provincial Legislature the Minister of Agriculture asked for and was given authority to purchase sheep for breeding purposes and to resell same to bona fide farmers at cost plus freight and incidental expenses. Arrangments for credit, where required, have been made with all chartered banks.

New Brunswick farmers who wish to purchase sheep for breeding purposes should apply to the Manager of their Bank before August 31st, 1918. The Manager will have the necessary forms on hand which must be filled out when an order is given.

A deposit of $3.00 per head on ewes and $10.00 per head on pure bred rams must be made when the order is placed with the Banker, when the sheep are delivered, where credit is arranged, an additional amount, sufficient to make the total cash paid equal to one-third the gross purchase price of the sheep, and a note for one year, will be required for the balance.

All orders must be placed on or before August 31st, in order that we may know how many to secure. Lambs will be purchased to a very large extent, because breeding ewes that are worth purchasing are not offered for sale to any large extent. Lambs will cost aproximately $13 to $15 per head and good rams about $40. No definite price can be set.

Strong, vigorous lambs will be selected and distribution will be made this fall as early as possible.

Competent men will select the sheep in all instances.

It is anticipated that many will pay cash, but for those who cannot, the Government has been able to arrange with the Banks whereby one year's credit can be obtained for two-thirds the gross purchase price of the sheep.

The acceptance of any order for sheep when a loan is applied for, rests altogether with the Manager of the Bank. All orders must be placed through the Banks.

This is an opportunity for many to commence in the sheep industry. Wool is, and will be for some time, a good price; mutton will likely remain high.

W. R. REEK,
Secretary for Agriculture.

FARM KEPT IN SLICK CONDITION

If the practice of cleaning up about the farm were as rigidly followed by the average farmer at stated intervals as the practice of house cleaninw is followed by his wife on scedule time, the general appearance of the farm would be greatly improved Of course, it takes a little time, but the satisfaction taken in the better appearance of the farm will prove sufficient reward for ahe time and effort expended. There are in nearly every neighborhood a few farmers to whom the neighbors refer as "slick" farmers, meaning that they keep their farms in a slick condition. Of course, this requires as much time and effort on their part as would be the case with the average man, but somehow this class of farmers are almost universally a prosperous class, while many who contend that they cannot afford the time to do the little things which will put the farm in presentable conditionns are not, which fact discredits the arguments of the latter class from a business standpoint. But, really, after one acquires the habit of keping the farm cleaned up, it requires little, if any additional expenditure of effort to keep it in that conditino. The habit however, can only be acquired with effort and the first thing that is necessary to that end is to have a general cleaning up at stated times, after the manner in which the industrious housewife does her cleaning.

The farmer who is careless of appearances will be surprised to note the amount of rubbish that has accumulated about his buildings, the number of things left in the wrong place, and the accumulation of odd jobs, which need doing to put things to rights and give the farm the neat and presentable appearance that is always admired by the stranger who journeys through a rural community.

Of course, there are extremes in everyahing, and it may not be profitable to go to the extreme in this direction, yet "straws show which way the wind blows," and the man who is habitually careless in this regard is apt to be found habitually careless in other details of good farming.—W. F. PURDUE.

USE FOR OLD IRON

Farmers who are going to do much concrete construction work should buy up all the old iron they can find. It makes a good reinforcement. Such articles as old buggies, wagon tires, shafting of all kinds, iron rods, etc., are usually sold on the first bid, and sometimes they aren ot even offered for sale. There is a good bit of junk around the average farm that might be disposed of for concrete reinforcing.

A bumper crop may mean a loss if your binder cannot handle it

At the same time your binder must be able to handle a light crop successfully—a thing some binders fail to do. The

FROST & WOOD BINDER

has practically grown up, in the last 80 years, with Canadian Agriculture and has been improved and tested until to-day it represents the ideal Binder for Canadian crops.

The crop won't wait—your binder must be ready

The Canadian farmer demands and must have a Binder that will cut any kind of crop—heavy, thin, tangled or straight—it must be light draft, easily handled and it must last for years with but little repair service. We have no hesitation in saying that the Frost & Wood Binder will live up to the highest expectations in all these respects. We use light, high carbon steel and put high-class roller bearings at every friction point so as to get light draft and strength. The reel can be moved by an easy, convenient lever to bring any kind of grain, tangled or not, to the cutter bar and once there Frost & Wood force feed elevators can be absolutely relied upon to deliver it to the binder, and the sure tying knotter. By another easy adjustment you can tie any size sheaf you want—and even the sheaf carrier is well thought out—lowering the sheaves gently and regularly to the ground so no grain is shelled. A Frost & Wood Binder is a guarantee that you'll get your crop in. Many are in use up to 20 years old, giving fine service.

This Binder question is a mighty important one. Be sure to read our illustrated Binder folder—ask our nearest agent or write our nearest Branch to-day.

Feed Situation This Winter Most Acute

Supply of Wheat will not Permit Flour Mills to Operate This Summer--- Great Shortage in Feeds Looked For

Where are feeds for the feeding season of 1918-19 to be procured,

This is one of the most serious questions that live stock owners will have to face in 1918-19. It is a problem which is causing the agricultural departments of all the Canadian provinces no small concern and it is one that is being dealt with vigorously in Ontario by the givernment of that province.

Just here it might be well to give a few of the causes for the serious shortage of mill feeds, which threatens to turn topsy turvy the usual methods of stock feeding and interfere seriously with the average supply of middlings, shorts and bran.

First, there is the fact that the exportation of wheat for the overseas forces has left litttle grain in this country for the use of the flour mills. The supply, until the new crop is harvested will be negligible. How much of this will be available for grinding in Canada, depend altogether on the needs of the men at the front. They must and will be fed. And the fact that wheat can be handled so much more advantageously than flour, at a time when ocean tonnage is so serious a factor in the winning of the great war, gives wheat the call as an exportable article.

Second. The order that all flour in Canada shall be war standard, means that the by-products of wheat have been reduced about one third. This has removed middlings from the market and leaves only shorts and bran to supply the demand. Here again there is a big shortage to be met.

Third. The order in force for some weeks, which prohibited the shipment of shorts and bran from wheat ground west of the Great Lakes, to any other but points in the west, cut the eastern supply very seriously.

Fourth. In the summer of 1917 hundreds of cars of straight feeds were shipped from Canada to the United States, despite the serious outlook for Canadian stockmen and despite the protest of the Maritime Farmer to the then food conroller, Hon. W. J. Hanna. This leak had a very serious affect on the mill feed supply in 1918.

Fifth. The United States corn crop, the largest on record, was not available for Canadian consumption until a few weeks ago. Transportation difficulties interfered with Canada getting he rusual supply of corn and the result was that thousands of tons of corn products, usually fed to Canadian stock had to be replaced by mill feeds.

Sixth. The United States government prohibited the export of cotton seed meal, except under license, and permits to ship this important feed to Canada were issued with care.

Seventh. The encouragement of increased production in beef, pork and dairy products has led to a far greater demand for mill feeds.

Eighth. Wheat products were in 1918 the cheapest feeds available and the farmers naturally turned to them for sustenance for their stocks.

Ninth. Difficulties in transportation were so serious that it was found impossible to move supplies freely. Not only was the rolling stock of all railways in great demand for moving war supplies, but the unusually severe winter made it almost impossible to get freights of any kind through.

These and other conditions have resulted in a feed shortage that promises to be worse before it is better. How to overcome it is taxing the ingenuity of widely interested bodies.

In Ontario, the department of agriculture has decided to supply farmers with special feeds, which will be furnished through various mills. This question of feeds is so highly important that we publish herewith a letter sent out by the committee appointed by the Ontario government to look into the matter.

The letter is as follows:

Toronto, June 4th, 1918.

Dear Sir:

The organization of Resources Committee of the Province of Ontario has definitely ascertained that there is likely to be a shortage of concentrated cattle and hog feeds in the Province of Ontario in the late summer and fall of this year, and with a view of supplying this shortage and with a view also of releasing to some extent some of the farm grown grain fit for human consumption, which would otherwise be used for cattle and hog feeds, have arranged that a certain quantity of ingredients such as oil cake, cotton seed meal, gluten meal and corn, which can be made into a concentrated and balanced cattle and hog food, may be exported from the United States and imported in to Canada. This arrangement has been practically arranged during the writer's visit to Washington.

As a means of having these ingredients imported into Canada, mixed, stored and distributed, it has been suggested that the millers are the ones who could best undertake the work and thus assist in the work of the Committee in conserving the resources of this Province as a war measure. It is thought that it would not be a sound business proposition for anyone to undertake to purchase and distribute in the wholesale may which has suggested itself to the Committee, unless that person or Company could handle at least sufficient of the raw materials to make 100 cars of the finished foods. The formula proposed to be used are as follows:

Dairy Cattle Rations

Hominy feed or corn	20%
Corn or wheat bran	18%
Cotton seed meal	19.5%
Oil cake meal	19.5%
Gluten feed	14%
Dried beet pulp	9%

Swine Ration

Corn	46%
Middlings	35%
Oil Meal	11%
Tankage	8%

It is further proposed that each person undertaking to go into this work should enter into a formal contract with the Committee somewhat upon the lines of the enclosed draft contract, which is sent merely for your consideration and suggestions and not sent as a contract finally revised.

I would be glad if you could let me know by return mail if possible and if not, at your convenience, whether you would be interested in this matter, and if so whether you could make it convenient to attend a meeting of the Resources Cimmittee and the Millers in Toronto on the 13th day of June, 10 A. M. at my office in the Parliament Buildings, to discuss and make final arrangements for the carrying out of this project.

Yours faithfully,
C. F. BAILEY,
Chairman of the Food Sub-Committee
Agricultural Section of Organization of Resources.

The agreement under which feeds are to be supplied, reveals co-operation between the millers and the consumer. Ontario is not to be denied her necessary supply of mill feeds and the work of organizing for sufficient to meet the demands of the stockman, was started months ago. The agreement between the millers and the committee, representing the Ontario government is as follows:

MEMORANDUM OF AGREEMENT made day of June, 1918,

BETWEEN:

THE UNDERSIGNED PERSONS, INCORPORATIONS AND FIRMS, hereinafter called "The Millers"

Of the First Part

and

THE ORGANIZATION OF RESOURCES COMMITTEE herein represented by the Chairman of the Agricultural Section thereof, hereinafter called "The Committee.

Of the Second Part

WHEREAS the Committee is constituted by an Act of the Legislature of the Province of Ontario known as The Organization of Resources Act, being Chapter 4 of the Statutes of Ontario, 6 George V., as amended by Chapter 27 of the Statutes of Ontario, 6 George V.

AND WHEREAS it is deemed advisable by the Committee and arrangements have been made for the permitting of the export from the United States and the import into Canada of certain articles entering into the preparation of balanced feeds for cattle and hogs to take the place to some extent of the farm grown grain suitable for human consumption.

AND WHEREAS the Millers have consented to act as importers, manufacturers and distributors of the said feeds and to make the necessary financial arranagements in that behalf.

NOW THEREFORE THIS AGREEMENT WITNESSETH THAT FOR valuable consideration the parties hereto mutually covenant, promise and agree as follows:—

1.—The Millers shall

(a) Purchase through one central personal agent, to be appointed and paid by them, the various articles or ingredients entering into the preparation of the said feeds, according to the formulae hereinafter mentioned, to the best advantage and from sources to be designated by the Committee.

(b) Assemble the same at convenient warehouses, or places of storage and there mix or prepare the said feeds according to the said formulae ,and have the same ready for sale on or before the day of 1918.

(c) Store the same pending sale and delivery.

(d) Sell, ship and distribute the same only to such farmers' organizations or such other persons as shall be satisfactory to the Committee and approved by it.

(e) At all times maintain the standard and quality of the said foods according to the said formulae.

(f) Purchase on or before the day of 1918 quantities sufficient to produce at least the number of tons of the finished product set opposite to the name of each hereunder.

(g(If required use bags or other packages to be supplied by or through the said Committee for containing the said foods for shipment.

(h) Permit the Committee or any person or persons authorized by it in that behalf to inspect the mills, warehouses and other places of storage, the books, invoices and other documents of the Millers at all reasonable times for the purpose of ascertaining the terms of this contract being carried out.

(i) Furnish to the Committee monthly statements of the quantities purchased, sold or distributed by each of the Millers and the quantities on hand, whether prepared or otherwise.

(Continued on paeg 600)

Millers Say Use Special Feeds

Serious Shortage in Bran and Shorts Will Force Use of Other Feeds---Review of the Situation

In view of the impending scarcity of mill feeds and the great demand which will have to be met from some source, the Maritime Farmer has asked several mills to give their opinion on the situation. The Campbell Flour Mills, Toronto, has kindly given a review of conditions, which is published herewith;

Regarding future outlook for feed. The big trouble throughout the country at the present time is that all feeders are trying to get Bran and Shorts and will not take up with the prepared feeds. The situation is just this. We have not enough wheat in Canada to keep the mills running beyond July. We, ourselves, expect to close down one of our plants the first of July and during June we have only run to about one half of our capacity. This condition is general throughout the country. Added to this we are required to make 76% flour and in making such flour we take considerable of the product that went into Bran and Shorts previously, into the flour, so that the capacity of feed is considerably reduced. The feeder, therefore, cannot expect to get enough Bran and Shorts to keep him going and he must look to some other feed this Summer at least, and possibly next fall.

We make our feeds from products of Corn, Barley, Oats and Rye, with Cotton Seed Meal, Oil Cake Meal and other heavy protein feeds added. These feeds are not mill rubbish put up under a special name in order to clear the mill of its waste, but are made of good, sound material. They are all registered products and carry a guaranteed analysis.

Monarch Hog Feed for instance, is guaranteed to contain 15% protein and 4% fat. We could make the protein content a great deal higher, but for the inexperienced feeder it would not be safe to make it stronger than it is.

Monarch Dairy Feed has a guaranteed analysis of 20% protein and 4% fat and this feed, like the Monarch Hog Feed, is made for general use, not alone for the scientific feeder.

Monarch Calf Meal is a high grade substitute for whole milk and can be used satisfactorily with either skimmed milk or water. The guaranteed analysis of this is protein 20%; fat 7½%.

Sampson Feed is designed for the general purpose of the farmer, that is, for feeding either cattle or hogs. In Monarch Hog Feed we use Digester Tankage and of course, this is not suitable for cattle feeding, so we make this Sampson Feed for general purposes.

There is no doubt that very shortly the farmers will have to depend almost altoether on such feeds as we have enumerated above, until the new crop comes in, in the Fall.

In Ontario the Department of Agriculture is cooperating with the mills in an endeavour to put out a standard guaranteed analysis feed for both cattle and hogs, the formula of which will be very much similar to the feeds we have described above. The mere fact that the Department of Agriculture up here in Ontario, where there are so many mills, appreciates the fact that Bran and Shorts are not going to be available would point to the fact that the farmers generally have to depend on some other feeds besides these for their feeding this Summer.

Cotton Seed Meal Situation

Prices will be Fixed by United States Government and Exports Regulated---Orders From Societies Should be Prompt---Selling Conditions

The acute situation of the mill feed market should make Cotton Seed meal a most desirable feed for 1918-19. Last year the Maritime Farmer purchased a number of cars of this high grade feed and delivered it in the Maritime Provinces for $49.50 per ton, 38½ per cent . protein. It was the best Cotton Seed Meal ever brought to this part of Canada. That at least was the decision of those who bought it. The supply was obtained from a United States mill, which was recommended by the United States Department of Agriculture. They guarantee quantity and quality delivered. This meal returns to the feeder about $15.00 worth of ammonia. Taking this into consideration, the feed is an economical one and should be largely used this winter. Some of the feed bought last year was held up by the railway congestion and was sold by order of the United States food controler. In order to avoid anything of this kind this year it is of prime importance that the orders be in early. They should be placed as near the first of August as possible. This feed is bought direct from the mill and there is no broker's commission on it. If your society is interested have your secretary make up the order at once.

These goods are sold in carload lots. The sales are conditional to the draft being paid on demand draft, draft, shipping order and bill of lading attached. That is to say the bill must be paid when presented from the bank. This may mean a few days in advance of the arrival of the car, but in case it is lost, the railway becomes responsible for the loss. In ordering have the bank notify the Maritime Farmer that the draft will be paid on presentation, on the above terms.

The following letter is explanatory of the situation:

The Maritime Farmer,
Sussex, N .B.
Gentlemen:

The by-produts of cottonseed is now in the hands of the Government and the price for the coming season of 1918 has not been set and will not be fixed until about August 1st, as we have been instructed by the Government to make no trades and sell no produce for the new crop until that time, it will be impossible for us to tell you anything definite. However, we can say this, that if the Government will permit us to ship any products into your territory, we will be very glad indeed to co-operate with you but at the same time, please let it be understood that any products that we sell to you will have to be sold, demand draft, shippers order, Bill of Lading attached, and just as soon as we know anything definite, will immediately get in touch with you.

Fireweed as a Honey Plant

Fireweed, or Great Willow Herb (**Epilobium angustifolium**) has produced large crops of white honey of excellent quality in direrent parts of Canad, especially after bush fires in soil rich in humus or clay. In the North Country this plant secretes more nectar than alsike clover. It comes into flower later than clover, after the colonies have had plenty of time to build up strong, and the honey flow from it lasts for about seven weeks during the best part of the summer In the Gatineau Valley, Que., and in the Temiskaming and Kenora districts of Northern Ontario, the honey-flow from fireweed commences about the middle of July, reaches its height about the middle of August and lasts until stopped by frost at the end of August or beginning of September. On the Pacific Coast fireweed is in bloom during June and July. Unfortunately the high yields from fireweed in many places do not last for more than a few years. Other vegetables springing up gradually chokes the fireweed, and the plant does not get another chance to develop a heavy growth and many flowers until after another fire occurs. After a bush fire, the surviving root stocks from scattered plants of fireweed creep in all directions, and the following year they throw up tall stems bearing the showy rose-colored flowers which keep opening, those that winter being succeeded by a ring of flowers higher up the stem. Although the bowers produce seed freely which will germinate in early spring, the seedlings perish except on ground that remains moist and shaded. Experiments are being conducted by the Bee Division to discover means by which fireweed may be made a dependable source of honey year after year. A stand of fireweed is being maintained by occasional burning, but this method whatever may be learned from it, can hardly be recommended on account of the danger of fires spreading. The most promising method at present seems to be the development of systems of beekeeping whereby the apiary may be easily transported every few years from a locality that is failing to one that is coming into profit. Many of the best firewood locations are remote from civilization, but as the bees can be kept so as to need no attention in winter, this is not a serious drawback, but the risk of losing the apiary in a forest fire must be guarded against.

Fireweed is particularly plentiful in many places in British Columbia, especially at high altitudes where it flourishes independent of fires, but the weather conditions are not so favorable for honey production as in parts where the summer is drier, less cloudy and warmer. For a good production of fireweed, clear moderately warm days with cool nights appear to give the best results.

At present, vast quantities of nectar secreted by fireweed in Canada are lost for want of bees to gather it.

Success in Co-Operation

The Co-operative movement in Canada has made remarkable progress during the past decade. At its beginning co-operation among farmers was almost unknown, but today it is well organized in all the provincse and the farmers are thus able to make their influence felt—not only in the commercia world—but also in the political world.

At this stage in the progress of the movement it is opportune to emphasize some factors which have been found by experience to contribute to success in co-operative work.

1.—Competent Management.

Co-operation attempts larger things. It aims to dispose profitably of all the farmer's products, as well as to purchase for him all his supplies. It proposes to sell for him his hay, grain, vegetables, fruit and other farm products and to sell them at a profit over and above what he could obtain through the ordinary channels of sale; it proposes also to buy for him his fertilizer, feed, etc., cheaper than he can buy it through his dealer; and unless co-operation can do this for the tiller of the soil, it has largely failed to justify its existence. Now to fulfill all these expectations and they are quite reasonable, requires, as you can easily see, not only experience but business ability of a very high order. To buy and sell wholesale for the farmers as proposed with market conditions such as they are today, demands a management such as is often extremely difficult to obtain in every community where a Co-operative Associtaion is needed. But such a management must be found if co-operation is to be a success for there is no more common cause for dissatisfaction with co-operation than mismanagement. Hence in the choice of a manager the greatest care should be exercised. Of course, the big man will command the big salary, but there is no man who is fully qualified for his office but can earn his salary many times over in the course of the year, while the incompetent manager can lose as much, so that the high-priced man is the cheapest in the end.

2.—Unswerving Loyalty on the Part of the Members to Their Association

The Co-operative movement comes into early conflict with the dealer. In the organization he quickly recognizes his most formidable antagonist and he at once sets about destroying it or at least to so weaken it that it will not seriously interfere with his business.

As a rule the dealer begins by offering the farmer a little higher price for his produce than the Association offers or he will sell to him the supplies he needs at a better rate He can even afford to make a pretty large sacrifice for the time being, if thereby he can break up the Co-operative Society, for when its opposition is removed he can in a short time reimburse himself for any loss he may have sutaied in his effort to destroy his rival. The co-operator ought to remember that this Association is his best friend, that it seeks his own interests and that the Association cannot live unless he gives it hi wholehearted support.

3.—Sufficient Funds in the Treasury to Form a Good Working Capital

Every Co-operative Asociation is a business organization and if success is to be attained, must be governed by strictly business methods. It is possible to do business without any paid up capital, but it is not saafe, for if losses occur, there is no contingent fund upon which to draw, in which case a direct assessment must be made upon the members, a process which is both expenive and exceedingly unsatisfactory.

The truly business-like way is to start with a sufficient paid up capital to conduct the affairs of the Company without depending too largely on your credit. This may entail some hardship at the beginning, but will in the end save much in Bank interest and other inconveniences known only to those who do business solely on the credit system.

If, then, these contentions are true and the experience of the past ten years has proved them true again and again, other things being favorable, Co-operation is bound to be a success if there is first an efficient management which is backed up by a loyal membership who supply that management with sufficient funds to form a good working capital.—H. S. Shaw, Berwick. N. S.

No Time to Quit Dairying

Europe is Slaughtering Milch Cows for Meat and Future for Canadian Dairymen Looms Gigantic

It is usually quite hard to convince a man what is good for him when his face is set in the other direction. In the same way, it is not the easiest thing in the world to lead an industry along the road heading for ultimate, rather than immediate advantage.

This is how it is with the dairy industry in Canada at the present time. It has a grouch on—no end of a grouch. It is kicking every inch of the way and, naturally, is not gaining much momentum. This is a pity, for its own sake as well as the sake of the soncumer.

In plain English, the dairy farmer is bidding fair to miss the best opportunity ever presented to him. He is being penny wise and pound foolish by putting the brake on an industry which should be one of Canada's greatest after the war. The trouble is that he is not looking beyond today. He is meandering around in a circle and failing to see his problems in the spotuight of national economic advantage. It does not take much perspicacity to realize that the dairyman who helps his country now is going to help himself in the future, and in war time personal relations must be subservient to the national cause.

The dairy farmer has taken cold feet and the consuming public has got to help him warm them up. He raised the price of milk and immediately people jumped on him—very unreasonably too. He had a whole lot of problems to meet that Mrs Housewife knew nothing about. If she had she would no thave been so ready to blame him. There is this to remember—that since the beginning of the war the price of cows has gone up 50 per cent., feeds 75 per cent., and labor 75 per cent. During this period the increase in the price of milk has been under 30 per cent.; butter has advanced about 40 per cent and cheese 50 per cent.

As the price went up, consumption went down. The dairy farmer was discouraged. He was having the time of his life securing labor. Five years ago the cost of labor on a dairy farm ranged from $25 to $30 a month. Now it is anywhere from $35 to $60 and hard to get at that. And for some time the dairy farmer has been asking himself: Is it worth it?

He has not seen his way very clearly and he has been kicking so hard that he has not had much chance to progress. He sees a cloud hanging over the dairy industry and feels the lack of appreciation on the part of the consumer. If the sky were as clear as in 1914; if the Atlantic were as free of danger; if there were as much shipping space available now as before the war—all would be well He would go ahead. As it is he can only see the difficulties of export and feel the lack of response on the part of the public. What he is discounting altogether ic the fact that after the war the dairy industry of Canada may be fairly expected to assume gigantic proportions.

And why?

Because Europe today, in her dire need, is killing off her breeding animals. This is the kind of thing that all nature rebels against. In the final analysis, she exacts her toll for such wanton destruction—but then it has to be, when there are starving people clamoring for meat.

Not only that. In the past Britain has imported much of her butter from markets which are now cut off for various reasons—Russia, Denmark, Norway and Sweden, for instance. Her dairy imports from foreign countries have far exceeded those from her own possesions.

In future she will lean more on her colonies for dairy products. AND OF ALL HER COLONIES SHE WILL LEAN THE MOST ON CANADA!

This is one salient point for the dairy farmer to remember when he is facing odds.

Britain's sortage of butter due to the war is 209.148.784 pounds. Of this vast amount Canada only sold 7,121.568 pounds to the Motherland last year. The disproportion is striking.

It is true that there are more milch cow si nCanada today than there were in 1914 but the numbers are relatively small when we cmopare them with the figures for such diminutive countries as Denmark, and in deed, England itself In 1914 there were 2,673.286 milch cows in Canada; today there are approximately 3.500.000.

Canada has only about one-seventh the number of cows of the United States. She has fewer than Great Britain and Ireland; fewer than France and not many morethan Denmark. The French cow population has fallen off by 21 per cent. as a result of the war. The British cow population is still normal.

Why doesn't Canada increase the size of the milch cow herds? It is a certainty that this European shortage will create an overwhelming demand not only for dairy rpoducts but also for cattle. Something has to be done to replace the 28,000.000 head that Europe has been obliged to send to the shambles.

Even as things are, our hold on European markets is gradually strengthening where dairy products are concerned. The following table of exports goes to prove this:

	1913
Cheese	155,216.000 lbs.
Butter	828.623 lbs.
Condensed milk	335,845 lbs.

	1917
Cheese	180,733,426 lbs.
Butter	7,990,000 lbs.
Condensed Milk	15,858.000 lbs.

Hon. T. A. Crear, Minister of Agriculture, sees great possibilities for Quebec and Ontario capturing much of the dairy trade of Norway and Denmark; while the aMritime Provinces besides saring in the markets of the old land should be able to command an ever increasing trade with the Eastern States in butter and cheese he believes.—I. M. Ross, Educational Division, Canada Food Board.

HELPS FROM SMALL THINGS ON THE FARM

The great variety of work on a farm demands that in order to accomplish the greatest amount of benefit from farm service one must have many implements and tools adapted to the various phases o fwork that is to be done.

While most men deem it absolutely necessary to invest in the more elaborate and expensive things of a farm, at the same time there are many others that are comparatively inexpensive and yet if not absolutely necessary are essential to the best interets of the work of the farm. For instance, on what percentage of farms will one find a decent outfit of small working tools? On many there is scarcely a good fork to be found, and only old things with bent or broken tines, chacked handles and half worn out, or blunt points. One cannot do good work with such tools. Good forks and plenty of them should be the rule, at least one for every man on the farm, and one extra for cases of emergency. Not only of one kind, but there should be forks for all purposes, hay forks, manure forks, ensilage forks, and forks for any other special purpose. These should all be kept in good order. If one is broken it should be replaced at once so that in case of emergency there will always be a means of supply available without loss of time, which is frequently of greater value than the price of the fork.

Of shovels and spades and hoes there should be a reasonable supply at least one of each kind and always in good condition, cleaned after use, wiped dry, oiled, and hung up in their regular place so that there will be no hunting when they are next needed.

On many farms there is no pick or crow bar. These are inexpensive articles, very useful now and again, indispensable for many purposes and all farms should include them in their working outlt.

Most farms should include a reasonable kit of carpenter's tools; at least, two good saws, a brace, set of bits, chisels, a large and small screw driver, plane, drawing knife, hammer, asortment of nails, tacks, screws, rivets, bolts, leather punches, cold chisel, pipe wrench, files and many other articles which one needs very often for making repairs or building new homemade articles.

Some farmers, but not a large proportion, could include a forge, drill, set of dies, anvil and other tools for iron working. The average farmer has not enough work of this character to warrant him in bothering with that kind of work, but he must do something along that line or run away to town every time a rivet gets loose or a bolt breaks.

In these days of wire fences a roll of wire and set of cutters is almost a necessity. Wire is one of the greatest emergency agents known. It can be used in a great variety of ways for repairing temporarily broken tools, implements, and machinery. A supply should always be kept on hand. A wire stretcher should also have its place here, both a single wire stretcher and fence stretcher. The latter can usually be borrowed or rented from the dealer from whom you purchase your fence, but one can never be sure of it, just when it is most needed. It is much more satisfactory to have one always ready when needed.

A good wagon jack is another useful little implement that comparatively few farmers posesss. Any handy man can make one in an hour or two and save a lot of bother in hunting up levers, etc., with which to raise the wheel from the ground to oil the bearing. Wagons are more likely to be oiled when they need it if a good jack is handy. A stone-boat may well be included amongst the small things of the farm. Few things will be used more than this if one is available when needed. In moving ligh tarticles about the farm for work such as field harrows, corn cultivators, barrels, boxes, stones and mony other things it would be thought indispensable on many farms. One of these useful implement scan be made by any handy person in an afternoon or on a rainy day at little expense. Three or four strong plank six feet long with some good cross pieces and a few bolts and nails will be all that is needed; or a couple of good crooks from the woods, or even two straight poles with the ends shaped up like a sleigh runner and covered with plank, either bolted or pinned on will do, and pay for the time labor, etc, many times over in a year or two.

Then how many farmers have a good grindstone? How can any one get along without one? Tools must be kept sharp if they are to be efficient and a good little tool of this kind is a splendid help on the farm The bicycle style is the best; for then one is independent of help. He can sit down at any old time and put his tools in working order without calling on anybody for help.

There are many other things, but these will suffice to point the way to better farm helps in some of the useful little things that can be had at small expense on the farm.

Rules Governing N. B. Standing Field Crops Competitions Season 1918.

Standing Field Crops Competitions will be held in the various counties of New Brunswick during the season of 1918 on the following basis:—

There will be four competitions in each county, viz:—

Wheat 1 acre; Oats 2 acres
Turnips, 1 acre; Potatoes 2 acres

The variety must be named when making entry.

An entry fee of fifthy cents will be charged for one crop and twenty-five cents for each additional crop entered by any one farm.

Entries will not be received for more than one variety of wheat, oats, turnips, or potatoes from one farm.

Entries accompanied by the saipulated entry fees must be lodged with the Secretary of each Agricultural Society on or before July 20th.

The Secretary of each Agricultural Society will forward all entries and fees thus received to M. A. MacLeod, Supt. Agricultural Societies, Department of Agirculture, on or before July 25th.

Entries not lodged with the Department of Agriculture before August 1st and entries not accompanied by the specified entry fees will not be judged.

The minimum number of contestants to constitute a competition in any one crop in a county will be five.

A przie will not be awarded on any crop that does not score 80 points out of a possible 100 points.

The number of prizes in each competition will be based on the number of competitors and the score tthey make as follows:

5 entries scoring 80 points or over $15
6 to 10 " " " " " " 30
11 to 15 " " " " " " 45
16 to 20 " " " " " " 60
21 or more " " " " " 75

The sum of five dollars will be deducted from each of the foregoing amounts and the balance will be divided pro rata among the contesants scoring 80 points or over.

To the highest awards will be added an additional sum of three dollars and two dollars respectively (these amounts constitute the five dollars deducted as above mentioned as a special inducement to aim for first place.

First and second prize winners will be required to exhibit their grain and roots at the Provincial Seed Fair, Fredericton, before the above mentioned additional amounts are paid.

The judging will be done by representatives of the Department of Agriculture.

Prize winners in the Standing Field Crops Competition will find it to their advnatage to select, clean and grade their surplus grain and offer it for sale for seed purposes and buy their feed oats if necessary. The growing of good seed grain is a profitable side line for the progressive New Brunswick farmer.

Establish a reputation for good seed and square dealing.

Sell no grain for seed that you would not wish someone else to sell to you nad all your seed grain supplies will readily sell at remunerative prices.

An entry in the field crops competition will start you on the right track. New Brunswick Departement of Agriculture.

M. A. MacLEOD,
Supt. of Agricultural Societies.

RECEIPTS FOR FARMER SUBSCRIPTIONS

The Maritime Farmer, instead of giving you one receipt in the year for a paid subscription, sends you 24, or one every two weeks. You will find it on the GREEN COLORED LABEL on which your address appears. The date printed thereon is that on which your subscription terminates. If on payment of your subscription the date is not changed within two weeks, please notify us. No other receipt will be sent.

JUNE 25, 1918.

DATES OF ISSUE.

November	5-19
December	3-17

NO MORE BONUSES SHOULD BE GIVEN

From time to time the dominion and Provincial Governments have been petitioned to grant bonuses to various enterprises. The applicants include public utility corporations, those holding semi-public franchises and others who carry on their businesses as close corporations. There has never been any evidence in Canada that these applicants are at all modest in their demands. There are in Canada many now influential men who have simply become wealthy and notable because of their ability to keep their hands in the public chest, which is another way of saying that they have had their hands in the pockets of nearly everybody in Canada. It is a more genteel method of picking pockets, that is all. It has often struck the Maritime Farmer as rather funny that a person's money, simply because it passed through the hands of a public treasury, should be invested in a different way from that which the original owner would have followed had he himself, made the investment. If a private individual takes stock in any corporation, he expects to receive an interest in the business and a stock certificate certifying as to his holdings.

When the Government takes stock in one of the hundred and one enterprises placed before it for consideration, it is expected to give, what are popularly known as bonuses. Just where the distinction should be drawn between a bonus and an investment is not quite clear. The Maritime Farmer believes that in future dominion and provincial governments giving railway subsidies, bonuses or whatever you may choose to call them, should receive stock certificates showing the amount of the government's interest and if dividends are earned by these concerns then the people of Canada or the people of the provinces interested should receive their share of the dividend. The creation of multi-millionaires, knighted baronets, etc., has been a rather costly investment for Canada and it is pretty nearly time that the thing was cut out. For instance, the people of Canada made McKenzie & Mann millionaires, by building the Canadian Northern Railway. Then the Government of Canada knighted them. Now the people are called upon to pay $10,800,000 for the common stock of the Canadian Northern Railway, a road which they have already paid for and well paid for. The whole system is an outrage and should cease.

STOCK FEEDING MUST BE CHANGED

In this issue of the Maritime Farmer is published an article on the mill feed situation which should be carefully read by all stockmen. tI shows that not only are mill feeds expected to be scarce this year, but that those in closest touch with the situation are making a most vigorous effort to overcome difficulties which are presenting themselves. Ontario, where the largest flour mills in Canada are located, has entered into an agreement with various millers to supply balanced stock feeds. These are to be sold at cost throuh a committee appointed by the Ontario Government to meet the increased difficulties of getting mill feed supplies. That steps were taken in Ontario some months ago to guarantee against disaster is most suggestive. It is a warning which should be heeded in other parts of Canada, including the Maritime Provinces. A representative of the Maritime Farmer was sent to Quebec and Ontario to look into the feed situation, and he found that in Ontario it had been decided that it would be unwise to depend upon the supply of shorts and bran to meet the requirements for feeds this year. If Ontario expects to be short in her supply of ordinary mill feeds, it looks as if Nova Scotia, Prince Edward Island and New Brunswick would suffer hardship in this direction. Present indications suggest that farmers in the Maritime Provinces must make up their minds to substitute balanced feeds for shorts and bran. There are many excellent feeds procurable but we have been so accustomed to using one or two kinds that the proposed change almost comes as a shock to the average stock feeder.

However, the situation has to be faced and met. The Maritime Farmer has been endeavoring to procure information as to balanced feeds, their content, keeping qualities and available supply. This information will be published later for the benefit of those interested in stock feeds.

KEEP ON PLUGGING

The ultimate heroism is not, as one might suppose, to enlist and march valiantly away to a post of duty "Somewhere in France." It is not the waving of flags, the singing of songs and the delivery of patriotic orations. It is not the purchase of a "Victory Bond" or a generous subscription to the Red Cross. The ultimate heroism may include all of these things, but is something which transcends them all. The finest heroism in the world is the heroism of endurance. Canada will not need an exhortation to courage in the trenches or on the seas, but Canada needs to-day and will need all through the war, the vision of the ultimate heroism that means quiet fidelity to routine task. How can be best serve the Nation? By quietly attending to our own business as if nothing unusual were happening, and by implicit obedience when the call to other service comes. We shall be better patriots in the ranks if we are good patriots on the farm. The world is full of bright men who are eagerly planning to do big things—when the right time comes. Their ideals are high—but they never get very far because in dreaming about the future they overlook the opportunities of the present.

Working for results leads to success, while simply waiting brings disaster. When good business-building ideas come to you, act upon them. Don't stop with planning. Develop your ideas—improve them—do something to-day to put them into action. Well laid plans are necessary for every successful undertaking, but they're worthless if not carried out. Do everything to put your plans into effect. If you do that, success is certain.

Success and efficient activity attract success, and receive voluntary help from unexpected sources. He who can be efficient and fruitful, if he stays where he belongs, becomes a mere cumberer of the ground when he strays into places where he has no real ties.

On the highway of time frequent obstructions are placed, which are nothing more than indicalots of progress, and every time they are passed they register your turnage of pluck. Anyone riding in an auto, looking far ahead and seeing a rise in the road, will recall at what a pitch the grade seems to be and to what a height it seems to reach; his attention is diverted and suddenly as he comes to the top of a slight range he recalls what he had seen and looks for it and discovers that the hill which had threatened to test the powers of the engine, when reached, resolved itself into an insignificant grade.

This holds true of most of the hardships and vexations of life; in the distance they loom large and threatening, but if faced and tackled they lose their strength on approach, and in nine cases out of ten their dangers and trials prove mythical.

Many people have sighed and thought or said: "I don't see why it is that everything he touches turns to gold." The men who seem to have the power to take hold of anything and make a success of it—turn it into gold if you like—do not have that power. Their successes only are talked about. Their failures they keep to themselves. They hide them, forget them. Heinz, the fifty-seven varieties man, failed two or three times, but came up smiling each time. And to-day he has arrived.

Stiffen your backbone, set your jawbone.

The ones who really deserve success keep on trying and in spite of reverses find the highway, broad and level and well lighted, that leads them straight to their mark.

It is quite a number of years since air brakes were first applied to trains.

Westinghouse called at the office of Commodore Vanderbilt, one of the railroad magnates of those days. He was denied entrance time and aain. Finally, however, persistence won him an interview. After he had stated his case, shown his drawings and was ready for his closing argument, Vanderbile sat back in his chair, fixed his deep set eyes on him and said: "What this really amounts to is that you think you can stop a train with air."

"That's just it," said Westinghouse.

Vanderbile pressed a button and a secretary answered the call.

"This man is insane. Throw him out and don't let him in here again," thundered the millionaire.

But you recall that air brakes are in universay use now. Suppose Westinghouse had accepted the dictum of the greatest railroad man of that day and given up his fight for recognition! The loss would be incalculable. The whole world would be the loser. Many thousand more lives would be sacrificed each year, millions of dollars would be wasted in wrecks that today are avoided because it is possible to stop a rushing train in a few hundred feet. Without the air brake we would have no flyers, no swift mail delivery; we would be without hundreds of things we now accept as a matter of course.

Keep on plugging!

General Use of Vegetables will Help Bread Our Soldiers

Selected by Mrs. M. A. MacLeod

With thrift as the national watchword, the business of every family is to save every quart and pound of foodstuffs that grow this summer in America. Not one bunch of beets or handful of beans not needed for daily consumption should be wasted. Boys, girls, and grown folks alike must do their share in stocking the family shelves with provisions of all kinds for the coming winter. "Grow and can" must be the slogan of all.

June is the opening month for canning, for then the war gardens are beginning to offer their patriotic gifts to the nation in the form of rhubarb, and strawberries, with peas not far behind. Do not wait for the close of the season, but put up the new things as they come along. If you have never tried canning young beets and carrots, there is still something delicious in store for you. Now, when so many persons are cultivating gardens, the city family has a better opportunity to buy vegetables fresh. Only with fresh products will there be success in canning.

The cold-pack method is the simplest and most successful way of canning. There are only a few simple rules which, followed, insure success. Too few housewives realize, however, that it is the preparatory steps which decide whether or not the canning is to be a success. Choose your jars and tin cans wisely. If your family is small, pint jars are best, for with them no food is wasted. For the larger family, quart jars are of course the only wise choice. The careful and prudent housewife will always test her jars before it is too late. If there are cracks, or if the cover and clamp do not fit tightly, failure is sure to follow. Fill the jars with water and see if there are any leaks; run your finger around the edge of the jar as well as the lid where the rubber rests. Is the glass smooth and without cracks? If the jar is of the Lightning type, adjust a rubber, put on the cover, and snap the wire clamp; be sure that it fits tightly. If you have Mason jars they should also be tested for leaks. Does your cover screw on tightly without a rubber? If it does not, there must be some defect. With tin cans test the leakage in the same manner. These tests are the only securities for your success in canning, and the wise woman will apply them carefully.

No less care must be taken with your rubbers. **Do not use your last-year's rubbers.** Old rubbers lose their elasticity, are brittle, and break when stretched. Too often, also, is the housewife tempted to use the rubbers which come with jars. Since the length of time that the rubbers have been in the jars is uncertain, the person of foresight will not use them. Buy new rubbers each year. Good ones may be hard to procure, but the best are none too good. Be sure that you can answer the following questions satisfactorily: Does your rubber fit tightly on the jar? Can you stretch it considerably and have it return promptly to place without changing the inside diameter? Does the rubber break when stretched? With jars and rubbers that stand these tests, the housewife is now ready for canning. Wash the jars and covers and tin cans carefully in clean, hot, soapy water, taking special care if they have been used the year previous. Rinse them in hot water—plenty of it—then place in a large pan, cover with boiling water, and keep them hot until you are ready to fill them. In the cold-pack method, sterilization of the jars is not necessary, for during the cooking process not only the fruit or vegetables but the jars as well are completely sterilized. The rubbers should be dipped in boiling water before you are ready to use them.

Can fresh vegetables! Can fresh fruits! Too much emphasis can not be placed upon the word "fresh." If you have no garden of your own, buy from a nearby farmer. It is a risk to buy vegetables from a market unless one is very sure it deals in fresh products. The fresher the vegetable, not only the more choice will be the canned product, but the smaller percentage of spoilage. Peas, beans, and corn should be canned within five hours of the time of picking. Then, too, of equal importance is the warning not to handle too large a quantity in hot weather. Do you realize that many of the failures in canning last season were due to the effect that people allowed their vegetables to stand, after being blanched, instead of packing them into the jars immediately? Remember a few jars each day well done are better than many jars carelessly done. Wash the vegetables carefully to remove all grit and dirt. Vegetables with thin skin like tomatoes may be wiped with a damp cloth. Greens are the most difficult to clean. These should be rinsed in several waters with a little salt added to draw out any insects that may be inside. Cauliflower and white turnips should be soaked in salt brine before blanching. Grade your fruit and vegetables. Imperfect fruit may be used for jams and jellies. For a few jars, the tightly covered kettle serves the purpose well.

With clean, fresh fruits or vegetables, we are ready for the next step. All vegetables and some fruits are blanched or scalded as a preliminary in the cold-pack method. The length of blanching varies with the product and may be done with either enough boiling water to cover, or steam. Perhaps a cheesecloth bag or large square of cheese cloth proves most useful, the washed product being tied up in the bag and placed in the boiling water to cover. The cheese-cloth bag is suited to all small vegetables and fruits such as peas, beans, greens, pineapple, etc. The wire basket is useful for tomatoes and other vegetables. With delicately flavored greens and green vegetables, the blanching is accomplished most satisfactorily in steam; by blanching in any other way you will lose the iron which makes green vegetables so valuable. Either a steam cooker or a colander placed over boiling water may be used for this process.

Blanching is an important step. First, it helps to insure a close pack by making the product flexible, as in the case of string beans, or by causing a shrinkage, as with greens. It partly eliminates strong acids, begins the sterilization of the food, and loosens the skins of certain fruits and vegetables, such as the tomato, In some cases it is impossible to give a definite time for blanching. The skin of young beets may be loosened in a very few seconds, but with older beets it takes a longer time; you must rely on your own judgment. But judgment is assited by a carefully tested time-table. **The cold dip** is equally important. It follows the blanching. Immediately after the removal from the boiling water, the fruits or vegetables should be dipped in and out of cold water. **The colder the water, the better.** This Treatment cools the food sufficiently to arrest all flow of juices sets the color, and makes it firm and easily handled, but it should not be allowed to remain for any length of time in cold water.

We are now ready to pack the product into the clean hot jars or tin cans. An aluminum funnel makes the process of filling very simple. With such vegetables as beans, beets and carrots, fill the jar closely, but without crushing, to within one-half inch of the top, using a spoon to insure a close pack. These vegetables may be canned whole, in section, slices or fancy shapes, as one desires.

The filling of the jars with boiling sirup or water is the next step. In the case of vegetables, one teaspoonful of

(Continued on page 601)

Home Canned Food is Safe

If You Follow These Directions

1. Seect fresh, clean fruits and vegetables or none at all.
2. Test every jar; even one crack spells sure loss.
3. Blanch. If the table says ten minutes, eight will not do it
4. Dip the product in and out of water—the colder the water, the better.
5. Pack clean hot jars with the cold-dipped product, adding salt to vegetables.
6. Pour on the boiling liquid to within one-quarter inch of top.
7. Place rubbers and covers and partially seal.
8. Sterilize the products the required time. Begin to count when the water boils.
9. Remove the jars and seal at once. Invert to cool.
10. Label, wrap, and store on a cool, dry shelf.

Time-Table

For Cold-Pack Method

	Time of cooking (Minutes)

Strawberries		16	12	10	5
Succotash	5-10	120	120	60	45
Tomatoes	1½	22	18	15	10
Turnips	5	90	80	60	40

These figures are for quart jars. When using pint or one-half pint jars deduct three or four minutes from the time of cooking given above. When cooking in two-quart jars, add three or four minutes to the time. For altitudes of 4000 feet or more above sea level, add 20% to 25% more time to this schedule. Individual judgment should be used, however, to increase or reduce the time, based on whether the fruit or berries are unusually hard or soft.

HORTICULTURE

THE THIRD SPRAY FOR NOVA SCOTIA APPLE ORCHARDS 1918

As in previous appications several formulas have been used for this spray, all with good results if properly applied.

Regular Formula.—Lime sulphur, commercial concentrate 1-50 (1.006 sp. gr.) with arsenate of lime 1½ lbs. to 100 gals. may be used for this spray if the operator is careful to direct the spray at the upper surface of the leaves and does not stand directly beneath the tree and spray upward. It has been found that drenching the under side of the leaves with lime sulphur at this time may cause a serious decrease in the crop, particularly in some varieties and under certain weather and other conditions. It should be remembered that leaves may be damaged by lime sulphur without any apparent external injury, whereas when burned with soluble sulphur they may be comparatively uninjured beyond the visible burned area.

In some isolated cases leaf yellowing was reported from the use of arsenate of lime and lime sulphur in the later sprays in 1917. This can be avoided by adding 10 to 15 lbs. of hydrated lime to the above formula. The advantage of lime sulphur arsenate of lime in cost, reduced leaf burning and elimination of sludge (lead sulphide) can thus be retained and this defect corrected.

Substitutes.—In using Bordeaux, the Thompson formula 2-10-40 is preferred by many to the old 4-4-40 formula, as it does not cause severe russetting of the fruit or yellowing or bronzing of the foliage. It may cause a certain amount of net russetting and very often will give a paler color to the fruit. Arsenate of lime ¾ lb. or arsenate of lead 2 lbs. to 40 gals. of spray may be used as in the preceding spray.

Some growers prefer a spray of soluble sulphur at this time as it is said to have none of the disadvantages of the other sprays, neither causing russetting or dropping of the fruit if properly used. The following is the formula:

Soluble Sulphur..... 3 lbs.
Lime .....25 "
Arsenate of lime.....1½ "
Water.....100 gals.

Modification for Green Apple Bug.

The same formula as recommended in the previous spray for green apple bug should be used here, viz: soluble sulphur 3 lbs. blackleaf 40, 1 pint and water 100 gals. adding about 4 lbs. of soft fish oil soap if obtainable. Poison in most seasons is not needed at this time and many biting insects will be killed by contact if the foregoing formula is used. Poison cannot be used with this combination. If it is necessary some other fungicide than soluble sulphur must be used and no soap added.

Modification for Bad Outbreak of Tussock Moths.

In many parts of the Valley, a tussock moth outbreak is at its height and in very exceptional cases of extreme severity a heavy spray of poison may be added to save the crop. In such cases a spray of paste arsenate of lead 10-15 lbs. to 100 gals. of water may be employed, depending on the fungicidal value of this poison to control apple scab. Yellowing of the leaves by the above formula may be avoided by adding 10 lbs. of hydrated lime but even a moderate amount of yellowing is preferable to defoliation or having from 50 to 90 per cent of the fruit injured by caterpillars.

Application

A fine mist spray is most suitable for this application except where it is necessary to spray for green apple bug. There are indications that in some cases a certain amount of mechanical injury has been caused to the young fruit by holding the nozzle too close to the tree. While most growers will prefer the spray gun on account of greater speed of application it will be well in using this instrument to stand well off from he tree or even better, on the top of the tank when using it. Direct the spray as before towards the upper surface of the leaves if using lime sulphur.

Pests Destroyed.

The arch enemy at this time as at all others is apple scab and in 1916 we have as a close second an outbreak of tussock moth in many orchards. In such places the modification recommended for this pest may be necessary. The codling moth, a minor pest in Nova Scotia, is best controlled by this spray. In the control of fruit worms and bud moths it is only second in importance to the previous spray. This application is also of value in the control of the so-called "pit rot."

Note

Do not use Arsenate of Lime alone, and when using with Soluble Sulphur use plenty of Hydrated Lime to prevent yellowing of the leaves.

Do not add Soap to a combination containing Lime Sulphur.

Do not allow Soluble Sulphur to stand exposed to the air. Keep in a closed container.—G. E. Sanders, Dominion Entomoloical Laboratory, Annapolis Royal, N. S.

SPRAYING IN THE ORCHARD AND GARDEN

This year, if never before, we must pay attention to the spraying of our fruits and vegetables. The high price of sprays and the difficulty in obtaining them, will discourage many growers from thorough spraying, but with the large increase of land under cultivation, spraying is doubly important in order to reduce the vast loss through insects and disease.

Three sprays are absolutely essential in the orchard:—the first, just as the blossoms turn pink; the second, after petals have fallen but before the calyces have closed; and the third, 10 to 14 days after the second spray. Other sprays may be necessary, depending upon local conditions.

In the garden, spray at the first sign of insects and disease and repeat at frequent intervals. Potatoes should be sprayed the first time when they are 4 to 6 inches high and four or five times more during the summer. Spraying is best done before a rain, in both garden and orchard, since it tends to reduce the danger of spreading the disease spores.

An expensive outfit is not necessary. A knapsack sprayer which can be carried conveniently on the back, will meet the needs of the small garden while a small hand barrel pump can be used for somewhat larger areas containing fruit trees. If you have no sprayer, get one without delay.

Many sprays are in use but the most satisfactory for the orchard is Lime-sulphur and Arsenate of Lead. Bordeaux Mixture and Arsenate of Lead are best for potatoes. For the small orchard, it is enerally more satisfactory to et a ready-to-use commercial preparation if possible, than to attempt home mixing.

Plan something definite in your spraying, by outlining the work and securing the materials before they are actually necessary. Too many wait until the necessity of spraying finds them unprepared. Delays in transportation are frequent at present, and a sudden demand for material leads to a scarcity as well as increased cost.

Send to your nearest Experimental Station for a Spray Calendar, and any information necessary regarding sprays and the method of application.

E. M. RICKER.

CONTROLLING OF POTATO DISEASES AT PLANTING TIME

Potatoes are plentiful this spring. Procure your seed from a field which produced a good heavy crop the previous year. The smooth appearance of the seed alone is no guarantee of a heavy crop. Disinfect the potatoes before cutting the seed. The plan adopted by the Experimental Farm is to soak them for three hours in a barrel containing either of the following solutions:

Corrosive sublimate: 2 oz. in 25 gallons of water. (Note: fatal poison to man or beast.)

Formalin: 1 pint in 25 gallons of water.

In cutting for sets, throw out all potatoes showing rot or brown spots, or rings near the stem end and in the flesh.

Cut the seed immediately before planting. The longer you keep them cut the smaller the yield. Be prepared to meet the ravages of the potato bug. Spray your potatoes. Spraying pays! Use poisoned Bordeaux mixture. The poison for the bug, the Bordeaux for late blight. This is the solution; 6 pounds bluestone, 4 lbs. lime, 40 gallons water. Dissolve bluestone first in 15 allons of water. Slake the lime in another vessel, strain it if lumpy. Pour both solutions together and make up to 40 gallons by adding water. Add arsenate of lead paste, 2 or 3 lbs. per 40

Fairbanks
Wagon Scales

are the practical heavy load scale for the farm as well as for contractors, builders, hay and grain dealers or coal merchants. They combine convenience, simplicity and accuracy. Fairbanks Wagon Scales fill every weighing requirement in

Capacities 5 and 10 Tons

Every Fairbanks Wagon Scale may be fitted with a Compound or Columbia Grain Beam, adaptable to graduations and standards required by the purchaser. Platforms are of steel frame construction and vary from 8 x 14 ft. to 7 ft. 11 in. x 22 ft.

Extension levers to carry beams 20 feet from scales are another convenient device obtainable at small additional cost, making it possible to locate the weighing beam under cover of an adjoining building.

Fairbanks Pitless Wagon Scales

are convenient and accurate scales for use where a pit is undesirable. The height of scale is only nine inches from top of platform to bottom of steel frame. This is an ideal scale for farm, contracting and quarry use. Capacity 5 tons.

All prices are exclusive of timber and foundations. Write our nearest branch for full particulars.

PULVERIZED LIMESTONE

SWEETENS THE LAND AND PRODUCES HEAVY CROPS

The demand last season for our "Clairmont" Brand Pulverized Limestone was so heavy we were unable to fill a great many orders. We expect a very heavy business for 1918 and would advise all booking now and getting their supply early. Our Limestone is showing wonderful results.

Fire, Lightning and Weather Proof

PEDLAR'S OSHAWA SHINGLES

THERE'S positive protection for the house that is roofed with these well-known galvanized steel shingles. The most violent wind storm cannot loosen them. The fiercest lightning will not damage them. Nothing can set them on fire. They cannot rust or decay. Why put on a risky roof when Pedlar's "Oshawa" shingles are available?

gallons of solution; or use 8 oz. Paris Green and 1½ lbs. of arsenate of lead for 40 gallons solution. Stir well and fill pump through fine meshed sieve. Particles will clog nozzles and are most annoying. Spray thoroughly, and cover all leaves well with spray. Don't drench. Commence as soon as the plants are a few inches high and continue every two weeks throughout the season.

For a large field use a high pressure horse-power outfit. For smaller areas there are many good hand sprays on the market.

Get your spray chemicals right away and arrange for the purchase of a sprayer; sometimes it is a good practice for several farmers to club together and buy a good power sprayer.

Watch the field, and throw out any sickly-looking or dying individual plants. Mark the one hundred best hills for future seed supply. From these select 80 which yield the largest number of uniform potatoes and plant these separately next year, and increase this practice until your strain yields highest in the neighborhood.

WHY ONIONS GO TO SEED

Onions grown from sets are not likely to go to seed if the sets have been properly grown and stored. Those sets which are a half inch or more in diameter are far more likely to shoot to seed than the smaller sets are. therefore, when sowing the seed from which the sets are grown, have it thick enough so that the seedlings cannot make sets that are too large. Furthermore, when the sets have nicely developed they should be gathered at once. If they are allowed to remain in the ground until the tops are all brown the root system will begin a new development. This may cause the heart to start just a little, so that the sets will not keep well in storage, and if they do keep fairly well they will have more of a tendency to shoot to seed. Good commercial growers shake their sets through sieves made of narrow slats. Those less than ⅜-inch in diameter are quite slow to start and seldom go to seed. Those less than ½-inch in diameter are also planted by themselves and all those too large to go through a ½-inch sieve are planted in rows by themselves because they start most quickly, are ready to harvest very early, and have the greatest tendency to bolt to seed. Thus, by having the large sets in a few rows the seed stalks may be more easily pruned away. If large onions instead of seed are desired these seed stalks should have the seed bud pinched off close to the seed bud where the stalk is small. If the seed stalk is cut off in the middle or lower, it leaves a large open hole. tl is supposed that if water settles down in this hollow stalk it may cause the heart of the onion to decay.

ORCHARD POLLINATION

It is conservative to state that the value of the honey-bee in cross-fertilizing the blossoms in the orchard is greater than the value of the honey production. Many fruit blossoms require cross-fertilization before they will set fruit, and the same thing is true of other plants, such a clover and buckwheat. While many wild species of insects serve this purpose the honey-bee is the only one which can be introduced economically to an orchard or farm, and, therefore, may serve as an insurance to cross-fertlization, if the weather permits their flight during the blooming period. Some have gone so far os to insist that no orchard can be properly and completely pollinated unless some stands of bees are kept in the district.

Bees, then, should be found in every orchard community, not soley because of their relation to the orchard, but because of the profit which the honey itself will yield, and with the scarcity of sugar, this is not to be overlooked. Therefore, at the present time, it is our patriotic duty to keep as many bees as possible. In some parts of Maine, bees are unusually successful.

Certainly repeated experiments have been tried to show that every orchardist needs the bees. Only recently an article was published concerning an orchard that only bore about 600 barrels of apples. Bees were bought and placed in the orhard, and since that time the same trees have borne 1800 barrels.

The Ben Davis is self-sterile. Some other varieties that are more or less self-sterile are: Yellow Bellflower, Roxbury Russet, Tolman Sweet, Gravenstein, King, Northern Spy, and Red Astrachan. Growers of these varieties will see that they must be pollinated in some manner, and certainly the bee is the cheapest agency, not asking but giving returns for its labor.

The past winter cannot be duplicated in forty years in its severity and length; even the late fall was out of season— therefore, the bees in Maine have suffered. Some beekeepers have lost larg quantities of their swarms, as the bees went into winter quarters without their usual late broods.

Frank H. Dudley,
Maine State Horticulturist.

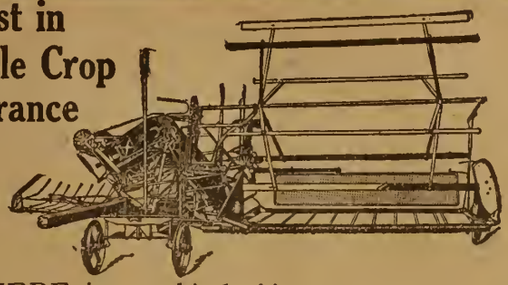
Invest in Whole Crop Insurance



THERE is one kind of insurance you may not know about, which requires no premiums, on which you realize every year, and which this year is fully as important as any other insurance you carry. **When your crops are ready for cutting, McCormick binders and twine insure the harvesting of the whole crop.** No matter whether the grain be heavy or light, tall or short, standing or down, lodged and tangled, a **McCormick** binder cuts and binds it all without waste. That is what we mean by whole crop insurance.

McCormick harvesting machines and binder twine, always efficient, are better than ever this year, when every bushel of grain is needed. Remember this when you come to buy your binder and twine for the season's work. Remember, too, that the larger sizes conserve labor. Buy the largest binder you can use, and buy a new machine if there is any question at all about the efficiency of the old one. A new **McCormick** binder is absolutely reliable.

You can be sure of having your new machine on time by placing your order with the local dealer as soon as possible, or writing the nearest branch now for catalogues. The dealer will appreciate having your order early so that he can give some service to your neighbors who delay. And the world will appreciate it!

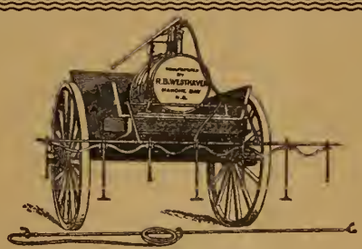
WHAT WILL YOU DO ABOUT IT?



Spray OR Suffer Loss?

"Perfect" Spray Pumps are made by

R. B. WESTHAVER, - Mahone Bay, N. S.

DO IT NOW

When a man ain't got a spray pump and is feeling kind of down.
Cause the pesky little insects won't leave his crops alone,
It's a great thing, oh my brethern, for a feller just to say
"Send and get a Perfect spray pump, and apply a coat of spray."

It makes a man feel queerish when the season's work is through
And the tatties are all blighted, and the apples wormy too,
Then order up a "Perfect" and do it right away,
And spray the fruit and tatties and save them while you may.

You'll never find another that does the work so well.
From the strainer up to handle, the outfit works just swell.
It has good agitation, and a real relief valve too,
It throws a spray that's perfect, and what more can it do?

Manufactured by R. B. Westhaver, Mahone Bay, N. S.

DAIRYIN.G

MILK FEVER AMONG HIGH PRODUCING COWS COMMON. IS QUICKLYY REDUCED BY SKILL

Milk fever is of common occurence among high producing cows. This was considered a very serious disease a few years ago, and in the majority of cases, the animals died. Today this condition is very rarely fatal.

Treatment for milk fever is strictly empirical, but it is certain that, even if we understood the causes of this condition, we could not treat it any more succesfully. There is no other disease in which the symptoms develop so rapidly and become so serious in such a short space of time as do those of milk fever, and yet, with our modern treatment the recovery is just as rapid and mystical as is the development of the disease.

This is a disease that cannot be determined by symptoms tlone, but the history and surrouding circumstances make diognosis possible. From wide experience the cow owner is able to know that the case at hand is milk fever and we may say that he arrives at his conclusion by intuition, but to the man who has seen several cases of this kind there comes to mind a series of symptoms that has in all probability been unseen by the attendant.

This is a disease of young cows, usually those having had one or two calves and, while it does affect old cows occasionally, it is not common. More often it follows an easy parturition and is rarely seen in cows that have experienced much difficulty in birth to their calves. Cows that are affected are invariably in good flesh and thrifty and are heavy milkers. The disease makes its appearance in the majority of cases within one to three days after th ecow has calved, but has benn known to occur before birth and as long as four to five weeks after calving. These latter two conditions are uncommon.

As a rule the cow is down when she is found by the attendant, but the line of symptoms that would be observed are pretty much as follows: The cow refuses to eat and stands without paying any attention to feed or surroundings. If she moves it is with a stiff, wobbly gait and it is noticed she cannot control her hind parts but weaves and staggers as she walks. The muscles begin to quiver and she shows all signs of having a chill. She will shift her weight continually from one leg to the other. In the course of an hour or so at most and often within the time after the ciw is seen she goes down; she lies on her breast, but is unable to get up; she seems very drowsy and rapidly gets worse until soon she is insensible and totally unaware of things that are going on about her. Her head is turned on one side and in this position she lies. Breathing is heavy and quite often moans and grunts as if in great pain, but this is not due to pain but rather the result of the insensibility that is present. There is very little milk to be found in the udder and the secretion of saliva is very scanty. There is no movement of the bowels or passing of urine during this time.

Warm water should be secured and an antiseptic solution should be prepared in which the milk fever apparatus can be cleaned. The cow is rolled into such a position that all the teats can be worked with by the operator; what little milk may be in them sould be milked out. The teats are then washed carefully in the antiseptic solution and the treatment is applied by means of a milk fever apparatus which consists of a milk tube to which is attached a small rubber hose. nI the center of the hose is a small metal chamber containing absorbent cotton saturated with a good disinfectant and on the other end is to be found a small rubber bulb or small metal pump. The milk tube is inserted into one of the lower teats and the teat is tensely distended with air; then the corresponding teat is inflated, and then the other two. To keep the air from leaking out of the teats, push the end of the teat in with the fingers. Do not use strings or rubber bands to keep the air in the teats.

This treatment is known in most districts simply as the air treatment, but originally these cases were treated by injecting into the udder solutions of potassium iodid in water, and then a salt solution, and this was followed by pure oxygen gas, to be later replaced by simple atmospheric pressure.

The cow should be treated just as soon as possible after being found, and even when she has been neglected so long that treatment might seem useless, she may recover. We have had cows in our practice that would recover perfectly after they were apparently dead. So in this condition as long as there is a spark of life there is good hope for recovery.

Under no condition is it advisable to attempt to give a cow suffering with milk fever any medicine by way of the mouth. The throat is partially paralyzed and the medicine might pass into the lungs and kill the cow.

In a short while after the cow's udder has been inflated she will begin to regain her senses; her breathing gets better and she gets brighter; after a while she will straighten up and swallow a few times and begin to act natural. As soon as she can be induced to attempt to get on her feet, she should be helped, and if she succeeds in getting up she should be steadied ofr a few minutes until she can stand alone.

A cow that lies stretched on her side when in this condition sometimes bloats badly and in this case should be tapped. It is better still to prevent bloat by keeping her propped up on her breast until she regains consciousness.

After the cow is on her feet she should have water, but no feed for the first ten or twelve days; at the end of this time she may be milked. No other treatment is necessary. If, however, the cow does not regain her feet within four or five hours infiate the udder as before.—Dr. G. H. Conn.

THE WATCHWORD FOR ALL DAIRIES IS CLEANLINESS

Cleanliness should be the watchword in all dairies regardless of the number of cows kept. The cow shed should be well ventilated, have plenty of light and all windows and doors screened in the summer to keep the flies from the cows while the milking is being done. It should be constructed for the cleanliness, comfort and health of the animals, the stalls should be the right length and the mangers the correct height for the comfort of the cows; the floor should be of some good material, some preferring cement, but a floor in a stable is damp most of the time, regardless of good drainage and bedding. The cement is always damp as one of its characteristics is to hold moisture anad it is also very cold in the winter and causes more rheumatism and other ailments in stock than most farmers give it credit for.

The milker and cows should both be clean before the milking is begun. A special suit for milking should be worn. Some put on old dirty clothes to keep their other clothing from ueing soiled, but such a practice should not be permitted. The milker's hands should be clean and he should not be allowed to smoke during milking, as th esmoke is apt to taint the milk and it is also dangerous if there is straw near. The milking should be done the same time each day.

The milk pails should not be made of wood as milk will penetrate the wood and soon become very unsanitary, even if they are well scoured and scalded. They should never be used for any other purpose and should be washed and scalded and put in the sun as sunshine makes them sweeter.

"Harnessing the Air" to Save Butterfat

The air is a great wizard. Properly employed, (as in a Sharples Suction-feed Separator) it will save North America more than eighty million pounds of butter which fixed-feed separators *waste* because 95% of them are turned below speed much of the time.

The Sharples Suction-feed principle really harnesses the air and makes it work for you. By means of the suction-feed, just enough milk enters the tubular bowl as can be *perfectly separated.* As your speed varies so does the suction-feed. Thus, Sharples saves the cream waste that results when fixed-feed separators are turned under speed.

SHARPLES
SUCTION-FEED
CREAM SEPARATOR

Skims Clean at Any Speed

While *air* is free to everybody, yet the suction-feed principle is exclusive with Sharples and fully protected. Bear that in mind when you investigate a separator and insist on knowing if it will *skim clean at any speed.* Get *proof.*

There are *no* discs in a Sharples tubular bowl which adds further to its superiority. The one-piece bowl is easy to clean, easy to turn—even for a boy. Write nearest office for catalog, addressing Dept. 79

DC-21

Some dairymen advocate the use of a strainer, that has gauze and absorbent cotton as a filter. No doubt it would do the work alright, but as cotton and gauze couldn't be used twice, it apears that to use as much cotton as that would take in a year, in just one dairy and multply that by several thousand (providing several thousand dairymen used it) as scarce as cotton is at the present time, such a practice would not be conserving the nation's cotton. On the other hand, a well-made strainer with fine mesh wire is as good as any. It is very convenient to have one made to lt the supply can of the separator and the cost is about $1.00.

The separator should be kept thoroughl yclean or the cream will be

It Pays to Use the Best!

252

Windsor Dairy Salt

Made in Canada

THE CANADIAN SALT CO. LIMITED

strong and make an inferior grade of butter. After it is washed it should be scalded and placed in the sun. Put the separator where there is no dust. As we go about the country we often see parts of a separator on benches or hanging on trees or fences near the road to sun, and the dust of the road so thick on them that you could figure on them. We wonder which is the more dangerous, the original germs or germs that are in the dust.

Milk and cream should be kept in a cool place in hot weather, and should not freeze in the winter, as freezing injures the quality. Not only milk and cream but butter also should be kept in a very clean place, free from any odors such as damp, musty cellar, poor cellar drains, anad even vegetables. Any odors whatever taint dairy products and lower their quality.

The churn in summer should be thoroughly cleaned and scalded (if the churn is of wood) then cold water poured in to cool it. By scalding the churn it prevents the butter sticking to the sides. After the butter is churned it should be washed and salted. For light salting put in three-quarters of an ounce of salt to a pound of butter, but one ounce is the amount usually used. One and one-fourth ounces to a pond of butter is considered as heavy salting. None but the best salt should be used. Never guess at th eamount of salt, but weigh the butter and then add the proper amount of salt.

In preparing the butter for market it should be packed in the best new, clean packages. They should be uniform in size and appearance. A package packed carelessly often condemns the best buttter. If the butter if to be packed for future use in the home, the sides and bottom of the tub or whatever it is packed in should be rubbed with salt. . Then put in a uqantity of butter, not more than can be firmly and evenly pressed to the sides, and continue until the tub is filled to within an inch of the top. Lay on a cloth wet with brine and one-half inch larger than the tub. Work the edges down and cover with about an inch of salt. Cover this with another cloth, put a tight head to the tub, then make a hole in the head and fill it with brine and keep it plugged tight. Keep it in a cool, dry atmosphere until wanted and the butter will be found good. Care sould be taken in choosing the article the butter is to be packed in.—M. P.

WATCH THE FARM SEPARATOR AT WORK

The separator should be watched. Be sure that the machine is level and securely fastened to a firm foundation. Remember that the speed of the separator is an important factor in its efficiency. If the crank is turner too slowly an excessive amount of fat will be left in the skim-milk. The milk should not be allowed to enter the machine until full speed is attained.

A temperature of 90 degrees F. is best for separation. If milk is cold when separated there is too much loss of fat. If the milk becomes cold it may be warmed by placing the can of milk in hot water. It is preferable, however, to separate the milk soon after it is drawn and before it becomes cold.

The separator should be kept clean if the highest efficiency of the machine and the best product is to be obtained. At the end of each separation flush out the bowl by pouring about two quarts of lukewarm water into the supply can. The parts may then be washed with scalding water, after which they should be allowed to dry. L. W. Morley.

It pays to crate-fatten broilers for 10 days if you are to sell them to customers or to dress them to ship, but it doesn't pay if they are to be sold alive to hucksters.—[Prof. Lester E. Card.

Don't Let Rough Roads Keep You from Riding

IT ISN'T NECESSARY. Hassler Shock Absorbers on your Ford will make "rough spots" feel almost as smooth as an even stretch of road. Their gentle, springy action absorbs every jolt and jar.

HASSLER PATENTED Shock Absorber For Ford Cars

Hassler Shock Absorbers make your Ford ride as easily as a $2,000 car. They increase tire mileage 20 to 100%, save gasoline, cut your up-keep bills one-third, and increase the resale value of your car. 300,000 Ford Owners recognize their economic necessity.

You can't realize how much difference they make until you try them. That is why we want to give you the opportunity to see for yourself.

10-Day Free Trial Offer

Phone, write or call for FREE TRIAL BLANK and we will have a set of Hasslers put on your Ford without a cent of expense to you. Try them 10 days. Then, if you are willing to do without them, they will be taken off without charge. Don't ride without Hasslers simply because someone discourages you from trying them. Accept this offer and see for yourself. Over 300,000 sets in use. Do it now.

WEANING TIME FOR YOUNG PIGS CRITICAL PERIOD

Weaning time is the most critical period of the hog's life. The approved practice is to wean at about six weeks. Teach the litter to eat three weeks before weaning, using a crib or creep which excludes the sow, or a separate pen. Feed, in a trough, preferably, middlings with skim-milk. With middlings at present unobtainable, finely ground sifted oats is best. Feed only small quantities at first and avoid having decomposed or stale food left over. After weaning, add shorts gradually up to equal parts, and from the second to the third month add barley or corn as one-third the total meal ration. First and last, avoid over-feeding with its consequent train of evils.

Within the last year at the Central Experimental Farm, experiment and subseuqent practice has indicated a system whereby weaning is simplified and the bad results of carelss feeding practically eliminated Instead of "hand-weaning" or feeding the weaning pigs milk and meal in a trough, a small self-feeder is substituted in the creep, skim-milg being fed in a separate trough Finely ground oats and shorts, and later ground elevator screenings witha small proportion of ground corn, if available, are placed in the feeder Thus, the little pig feeds himself when and as much as he sees fit, is able to eliminate from the meal eaten much fibrous material which he must consume willy-nilly where fed a slop, and incidentally accustoms himself gradually to skim-milk. Except in cases of early litters, the little pigs are given access to outdoor runs at all times from two to three weeks of age. Excellent growth is shown, the pigs developing clean, long, and thrifty, with no evidence of thickness, pudginess or lack of energy. Absolutely no evidence of indigestion or scouring has been seen, and in one instance where a dozen litters were so fed at a central feeder the percentage of "culls" was remarkably low. When finally removed from the sow, pigs so weaned, particularly where they are to be self-fed subsequently, give minimum evidence of the check in growth, usually Incidental to weaning in a greater or lesser degree. In short, while the experienced hogman can hand-wean his pigs with maximum results, the farmer lacking experience or depending upon attendants, is likely to run into difficulties. The method described besides reducing labor apparently removes the danger of overfeeding. Both method and results might be described as automatic.

In the foregoing method, skim-milk plays an important part. Where this or other milk product is unobtainable, experimental evidence would show that good pigs may be raised by following this method and supplying tankage, blood-meal, fish meal or some similar animal product in a separate compartment of the feeder, not mixed with the regular meal. Pigs, so fed, have shown only silghtly inferior in quality to skim-milk fed lots, but the cost to produce would seem to be considerably increased.

CO-OPERATIVE MARKETING OF WOOL VERY SATISFACTORY

J. D. Thompson, expert wool grader, representing the Livestock Branch at Ottawa, assisted by J. K. King, B.S.A., another representative of the Livestock Branch, have finished grading the wool accumulated at the Fredericton warehouse and have classified it as follows:

Fine medium	5. %
Medium	53. %
Low medium	34. %
Coarse	3. %
Rejects	.4%
Tags	.4%

On June 11th the wool valuators from Ottawa and Washington, accompanied by T. Reg Arkell, Manager of the Canadian Co-operative Wool Gorwers, Limited, Toronto, appraised the wool at Fredericton warehouse and placed the following valuations on the various grades:

Fine Medium	81¾	cents	per pound
Medium	78¾	"	" "
Low Medium	73¾	"	" "
Coarse	73½	"	" "
Rejects	54	"	" "
Tags	28¼	"	" "

Thtse prices are very satisfactory to the officials of the Department at Fredericton and undoubtedly will be equally satisfactory to those wool growers who have participated in this co-operative undertaking.

It will be noted that the major portion of the wool has graded as low medium and medium and that the price ranges from 73½ cents to 78¾ cents for fine medium. These prices are less freight to Boston, which will amount about one half per cent. per pound, thus giving and average price of from 7g-76 cents for wool in the grease.

The wool accumulated at the Moncton warehouse has graded slightly higher than that at the Fredericton warehouse, consequently the wool growers in the Moncto ndistrict will receive a higher average price for their wool than those wool growers in the Fredericton district.

The two warehouses at Fredericton and Moncton will continue to take in wool during the entire month of June, thus giving wool growers who have held their wool an oportunity to market through the Co-operative Association.

SUPPLEMENTING THE COW PASTURE

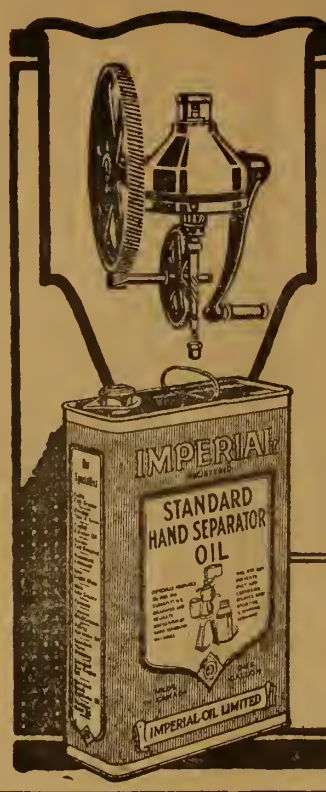
With coarse grains at abnormally high prices the question of many dairy farmers as to whether or not it will pay to feed concentrated feeds of any kind to dairy cows while on pasture.

Given an abundanse of good pasture, experiments at Macdonald College have proved that, it will not pay to feed the average dairy cow grain. With limited pasture and a summer of extremely unfavorable weather, it will pay to feed milking cows something besides the pasture. If soiling crop or silage is available, conentrated feed is less important, but for the best returns from every standpoint a combination of the two is necessary.

The prevailing practice in many districts is to depend upon pasture entirely. For the average cow having as she does small milking capacity and usually quite a territory of rough pasture, it is questionable if grain feeding will pay under present codnitions. On the other hand when farming is more intensified with less acreage in pasture and better cows, it is absolutely necessary and it will pay to supplement the grass when it gets short with at least a limited amount of grain feed.

The time to commence feeding is just when the cows begin or even a little before they begin to shrink because of short pasture. If feed is delayed until the cows have materially decreased in milk and flesh the results from feeding will at first be disappointing and will continue so until the cows regain normal condition. This fact explains many of the apparently poor results fro extra feedings.

The amount of feed necessary must depend on the cow's work, her condition and what else she is receiving, In the average case three to five pounds of meal per day will suffice. At the present time it is often a case of taking what meal may be available and mixtures are almost out of the question. Oil cake meal seems about as good value as anythink and less of it will do. It is a good milk producer, and is a splendid feed for sustaining and increasing body weight. If other feeds can be combined with it so much the better, but one pound of it per day even alone on short grass will go a long way in tiding the cows over a bad time.



THE BEST OIL IS CHEAPEST

WHETHER your separator runs hard or easy will tell in your profits. The easier it operates the less wear, the longer durability, the surer the returns on your investment.

Remember—it's the gears and bearings that take the wear. Lessen it with Standard Hand Separator Oil—made specially to reach and lubricate the revolving parts. Pure, highly fluid, non-gumming. As necessary as a special oil for your automobile.

Sold in pint, quart, half-gallon, gallon and 4-gallon cans; also barrels and half-barrels. By reliable dealers everywhere.

RHEUMATISM IN PIGS

Rheumatism in pigs can be generally attributed to cold damp pens and exposure, but it may occur in hogs that are well cared for. Overfeeding is also said to cause it. Specific causes unless it is in articular rheumatim, should not be considered in discussing the disease.

The symptoms are quite marked. These are fever, loss of appetite, lameness and general lack of condition. Sometimes large swellings appear in the region of the hock, knee and joints of the feet. nI acute rheumatism the pain in the affected muscles and joints is intense.

Preventive treatment is very important. It means the providing of dry comfortable quarters and the avoidance of exposure. Unless this is practised but little good can be gotten from medical treatment. A sloppy diet is also paluable. Salicylate of Soda is the most useful drug to give in this disease. The dose is 20 or 30 grains in the feed or as a drench, three times a doy. Larger doses and at more freuqent intervals may be given

DIARRHOEA
WAS SO BAD
Could Scarcely Do Work.

Mrs. O. Pritchard, Elora, Ont., writes: "About a year ago I was troubled very much for a whole week with diarrhœa. It was so bad some days I could scarcely do my housework. I took two or three different kinds of medicine, but got no relief, and was just at the point of going to see the doctor when I explained my case to a friend.

She put a half bottle of Dr. Fowler's Extract of Wild Strawberry in my hand and said: 'You take this and you won't need any doctor.' Before I had emptied the bottle I was cured, and have never had any return of the trouble. I can truly say that 'Dr. Fowler's' is the best medicine I have ever used for diarrhœa."

Dr. Fowler's Extract of Wild Strawberry is not a new or untried remedy, as it has a record of 72 years of cures to its credit, and is recognized on all hands as the only reliable remedy ever offered to the public as a safe and certain cure for diarrhœa, dysentery, colic, cramps, cholera, cholera morbus, cholera infantum, summer complaint and all looseness of the bowels, whether of children or adults.

It is particularly good for teething babies.

The price of Dr. "Fowler's" is 35c. a bottle, and we would warn you against accepting any substitute. Many of these are positively dangerous, and you are risking your life when to take them. The genuine is manufactured only by The T. Milburn Co., Limited, Toronto, Ont.

in an acute attack for a short time. Quinine and bitter tonics can also be given. Blistering ointments and liniments should be applied to the inflamed articulations.

AYRSHIRES SELL WELL

The Annual Consignment Sale of the New England Ayrshire Club was held at Charter Oak Park, Hartford, Conn., on June 11th and 12th and was largely attended. The bidding was brisk and competition keen, there being many purchasers for each animal. The average price for all animals in the sale was $400 and the highest price paid for a single animal was $4200.

The Canadian Ayrshire breeders were well represented, R. R. Ness, Howick, Que., consigned 6 head which averaged $890, "Barleigh Right Kind" (Imp.) selling for $1225. Hunter Bros, Grimsby, Ontario, also consigned 6 head, which averaged $1200, among them "Lochfergus Cherry" (Imp.)—33297—selling for $3750, and "Lady Mary"—37565—bred by D. A. Macfarlane, Kelsoe, Que., selling for $1200. Gilbert McMillan, Huntington, Que., consigned 3 head, which averaged $645, "Grasmaller's Flora" (Imp.) selling for $875.

(A fuller report of the sale will appear in a later edition.)

KEEP A PURE BRED BULL

Because

1. Cows are known by the "company" they keep.
2. Every calf has a right to pe well born, and the use of a grade bull is an infringement on this right.
3. He has a good and authentic record behind him; the grade has nothing but his tail.
4. There is no sale for the offspring of a grade bull among men who pay good prices for stock.
5. A purbred bull will sell at any time for any purpose for as much as a grade, and usually more.
6. Mr. Milkman, you should raise your stock and the use of a purebred bull is the first step in the right direction.
7. Except for the element of the risk, the cost of keep is no greater for a scrub or grade.—H. E. JUDKINS.

RID STOCK OF LICE

There is no better way to rid stock of lice than to wash stock thoroughly in a two to five per cent. solution of a coal tar disinfectant such as zenoleum or creolin. This should be repeated in about a week after the first washing. The animals should be rubbed dry after washing, then should be blanketed to keep them from taking cold, being especially careful in the matter in cold weather.

If the animals are to be kept free from lice, the stables should be celaned up being thoroughly disinfected, and provision for light and ventilation should be made.

PROPER MEANS TO SAFEGUARD GREAT INCREASE OF PIGS

The efforts to increase the number o fhogs will not bring about the desired result unless proper means are taken to safeguard both the sows and the pigs against disaster at the critical time of the arrival of the pigs.

Preparing Beforehand

Every farmer and breeder should keep a record of the date on which each sow was bred, and make a correct calculation that sixteen weeks from that day a litter of pigs may be expected. At least a week or ten days before the day when the pigs are expected the sow should be supplied with a pen by herself that is not very large but is warm and free from cold draughts of air. The reason is because it will take at least a week for the sow to become wonted to her new quarters and feel at home, a matter of considerable importance as the homelike feeling will prevent restlessness, which is a dangerous difficulty at this time.

Be sure and attend to giving the sow the proper feed to put her system in right condition. Do not feed her heavily, but give just what may be termed a moderate amount of food materials. The feed should contain some light rations like wheat bran and middlings, wihch put the bowels in a laxative condition. A small amount of vegetables like mangels, beets or small potatoes, say two or three pounds each day, will be of great benefit in several ways. It will cool the system and encourage the secretion of milk at the right time.

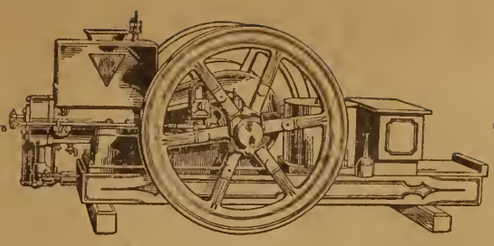
The bedding should not be too plentiful or coarse, as little pigs soon after they arrive are liable to get strangled with coarse litter and get discouraged about getting to the udder. If the bedding is abundant the pigs often work under it and get laid on.

At Farrowing Time

It is best to make all preparations beforehand and at the time the pigs are to arrive keep away and leave the sow to herself as a little disturbance at this time will often prove detrimental.

Feeding the Sow

While the sow should have a moderate amount of feed before farrowing, all feeds should be kept away from her at this time. Remember that she is sick and her system is not in condition to digest food. Do not feed her any heavy feeds at this time, and do not feed lightly for at least twelve hours after farrowing. After her sickness has disappeared a little sloppy drink can be given. When she gets up and manifests a desire for food begin by giving her a small quantity of light feed, largely sloppy feed, and increase gradually as she seems to desire. Do not attempt to get her on to full feed under a week's time. Bad results are sure to folliw if heavy feeds are given soon after the arrival of the pigs. If the sow is not seemingly injured by heavy feeds at thi stime, the pigs will be. It is not safe to take any chances in this respect.—N. A. CLAPP.



ALPHA GAS ENGINES
faithful as a work-horse

DEPENDABILITY is the keynote of the Alpha. It RUNS when you want it to — chugs away all day and you never need to think about it.

It's always reliable; always ready.

Why?

Because it's so simply and sturdily designed and so expertly and honestly built.

There's nothing complicated about the Alpha—no electric batteries; no delicate attachments to "keep you guessing."

Just oil it; turn on the fuel—either gasoline or kerosene—and the Alpha does the rest.

It takes a whole lot of the drudgery out of farmwork, and, in addition, saves time and fuel.

JUST ASK ANY ALPHA USER

Alpha Gas Engines are made in 12 sizes, 1½ to 28 H. P., and in stationary, semi-portable or portable style, with hopper or tank-cooled cylinder.

Write today for our gas engine book

FEEDING ROOTS TO HOGS

What is the relative feeding value of mangel wurzels, sugar beets and Oxheart carrots for hogs?—F. L. G.

In 100 pounds of sugar beets there are 13.5 pounds of dry matter, 1.3 pounds of digestible protein, 9.8 pounds of digestible carboyhdrates, and .1 of a pound of digestible fat. For carrots the figures run 11.4fi .8, 7.7 and .3 respectively, and for mangels 9.1, 1, 5.5, .2. Thus the sugar beet has the most dry matter, a little more digestive protein, and quite a bit more digestible carbohydrates. They would rank as hog feeds in the following order: sugar beets, carrots, mangels.

Probably the greatest mistake made in feeding roots to hogs is in giving them too great a quantity. Roots are very bulky, being approximately 90 per cent. water, and it is not advisable to use them for fattening hogs in a greater proportion than one-fifth of the ration by weight. They are particularly valuable for stock hogs, and for brood sows during the early part of pregnancy, but during the last 6 to 8 weeks before harrowing sows should not be fed a heavy quantity of roots, as they require concentrated feed for the growth of the young and the production of milk. Stock hogs and dry sows can be run through the winter on roots and alfalfa hay without any grain.

As to whether one should choose sugar beets or carrots for this purpose will depend quite laregly upon the yield in his own locality. When roots are to be fed heavily to stock hogs I would prefer the carrots to the sugar beets, in spite of the smaller quantity of nutrients in the carrots, because sugar beets have a peculiar biting pungency which attacks the throat to some extent when animals are fed heavily on them.—G. E. Morton, Colorado Experiment Station.

"Camouflage cattle"—you know the kind that looks good to the man in the street, but won't make the most of the feed they get—are slacker cattle, and the men who produce them are slacker cattlemen.

DOUBLE DAILY SERVICE TO PRINCE EDWARD ISLAND

All Rail Short Route

Tormentine—Borden aand Car Ferry

With the Summer Time Table in effect June 2nd, there will be a double daily service between the Mainland and Prince Edward Island. Passengers by the Maritime Express from Montreal and the morning expresses from St. John and Halifax will be able to arrive at Charlottetown 7.05 p. m., Summerside, 6.05 p. m., and Tignish 9.35 p.m. By the Ocean Limited from Montreal, the Boston express via St. John passengers will arrive Summerside at 11.00 p. m. and Charlottetown 11.20 p. m. From the Island by leaving Summerside at 6.30 and Charlottetown at 6.00 a. m. passengers will connect with the Ocean Limited for Montreal, the express for Boston and the Maritime Express for Halifax. By leaving Tignish at 9.30 a. m., Souris 6.45 a. m., Charlottetown 1..50 noon, and Summerside, 1.30 p. m. passengers will connect with the Maritime Express for Montreal.

GROOMING AS NECESSARY TO THE WORKING HORSE AS FEEDING AND WATERING

If there is one duty more than another that is neglected in the stable it is grooming. The usual fate that overtakes the colt on the farm, destroys more than the breeder's art can catch up with in the supply effort. It is a process similar to the present struggle between the German U-boats and shipbuilding yards in Britain and America.

The Neglected Horse

Much of the destruction of horse energy on the farm comes from the neglect of the horse's toilet. Some of this carelessness is not altogether due to wanton neglect, but more through a lack of knowledge of the necessity of thorough cleaning and grooming. It is either counted as an unnecessary bother or excused out of ruling owing to lack of time. 8he farmer who is alive to the value of cleaning the horse finds the time and oportunity to do it. It does not take a long time when the right way is taken. Time can be misspent by grooming the parts that could best be done without, and neglecting the parts that most resuire it.

As soon as the colt is old enough to be put into harness, the object seems to be, in many cases, to wear him out or break his spirit as soon as possible. He is often worked hard all day, hastily put in the stable, fed and blanketed without being permitted to cool off, if blanketed at all, and left for the night without cleaning body or feet. The sweat saturates the blanket and the colt remains damp all night, the mud chills the legs and lessens the circulation, and foreign materials collect in the bottom of the feet, heat and keep the sole in a feverish codition. The next morning the driver comes to the stable, feeds removes the blanket, and with the comb curies the body a very little, the legs practically none and entirely neglects the feet, then harnesses the colt and goes to work. At every step the colt betrays his care; he is stiff, his joints are sore and his courage gone.

The Neglected Parts

While the teamster often takes much interest in rubbing the body and in keeping the hair well brushed out, the legs and feet are neglected, though really of most importance. The legs are the most exposed to water and mud, often remaining soaked the entire day, and to the ever present dust of summer. They are subject to very severe strain and concussion, and if they are to be kept sound they must be thoroughly cleaned and well rubbed so as to encourage the circulation and keep the parts warm and dry. This should be done every evening after a day's work. Nothing contributes more toward producing disease and unsound limbs than allowing the animal to remain all night with damp and dirty legs, especially in damp or cold stables. The cleaning and rubbing of the skin stimulates the secretions and improve the general tone of the entire system, but more especially upon the feet and legs.

The Correct Way

When the horse comes in at noon or night wet with rain or sweat, his hair should be evened down the natural way, and it will remain so when dry and is then easily cleaned. If it is allowed to dry when all swirled up it will remain so, and double the grooming will be necessary to make the coat sleek and clean. When a horse is wet with sweat his hair should at once be evened with a brush or stripper. It is no use using a curry comb at this stage. Allow him to cool off a little, then blanket him. His legs, if wet and covered with mud should be rubbed with cloth or straw to partially clean them; the hair should be evened in the same manner as the body. Later, when the blanket is removed, at last visit to the barn at night, the horse should be well groomed, the dust will be more easily brushed from the hair at this time than any other. If left on the skin the dust will find its way to the skin, and subsequent sweatings make it into grease and paste that serves as a medium for excessive sweatings and weakening of power and loss of spirit. When grooming, there is generally undue use made of the curry comb to raise the dust for the brush to extract. Some horses with tender skins feel this keenly, and the severe ordeal with the comb does them harm. If the horse is groomed at the right time—just when newly dry after sweat or rain - the brush will be sufficient to do most of the grooming on the body and the curry comb should be used mostly to clean the brush at every stroke when necessary.

Grooming the Feet

No horse has been properly groomed, however much time is spent on him, that has not had his feet examined. There are more lame horses through this neglect than any other cause. The daily examination and clean out with pick should remove all the dried mud and gravel that accumulates and sets up corns, thrush and similar troubles. There are more corns in the feet of horses than the average driver or owner ever dreams of, and the cause is chiefly through neglect of this part of the grooming duties.

A daily scrutiny of and cleaning of the feet will prove a medium of education to the horseman of the structure and growth of the hoof and will show when it is necessary to relieve the hoof by having shoes removed. The gravel stones that gather and are pressed by the baked dirt on the sole or frog are the cause of wet corns. They are formed by th ebruising caused by small stones either pressed by hardened filth or jammed between shoe and hoof. The horn overlying the bruised part becomes saturated with pus,, cracks and allows dirt or small particles of gravel to enter. The pain during the process is terrible and ultimately the horse becomes lame and at times unable to bear weight on the diseased foot.

Only Five Minutes Each Day

Gravel cannot make its way into the foot when the horn is sound; it is only when the sole becomes diseased, heated and soft by accumulated dirt and badly fitting shoes that gravel gets the chance o fdoing the damage and causing pain.

In lifting a foot to examine it sometimess a pinkish spot is seen in the sole. Severe bruising from an ill-fitting shoe or by stepping on a sharp stone with full weight will cause this inside bleeding, and the blood is absorbed by the sole horn, as ink is absorbed by blotting paper, and becomes stained red on that account. The after effect of this condition is dry hardened hoof, in which nutrition for the foot is stopped. Some farmers who notice this condition rub oil and grease over the hoof with the mistaken idea that it will bring them back to their growing condition. Never put oil on the feet, as that prevents the water from entering the hoof wall. The foot is like a sponge, very porous and sensitive to water, and will not stay in perfect order without moisture. Oil and grease clog the pores.

There are very few horses that have bad feet from inheritance, all their troubles come from neglect. Five minutes every day spent with an examination of the feet of the working team will put them right. It is time that must be spent before the daily grooming operations are complete.

PREPARING TEAMS TO STAND THE HARD WORK

On every farm where horse flesh is the motive power, there is one problem that comes once a year, namely, the preparation of the teams so that they can stand the hard work of spring and summer without a blemish resulting, such that the value of the horse is not greatly decreased and the ease of working it greatly increased. One of the first tteams I ever drove had in it

an ugly horse and his disposition had been thus re-arranged because somebody had sometime erred in not having him properly hardened when he started in with the spring work. This horse was a big fellow, abundantly able to work, but the moment the least break in the skin came on either side of his shoulders, the only way he could be put into the collar was to buckle it and slip it on over his head.. Even at that he would do considerable jolting about when the harness was put on him, and of al the unpleasant beasts to work, this horse beat everything I ever tried. He never would take hold until the other horse started the load, and all this might have been averted by a little judicious care in handling. I know this to be a fact because neighbore who knew the conditions said so.

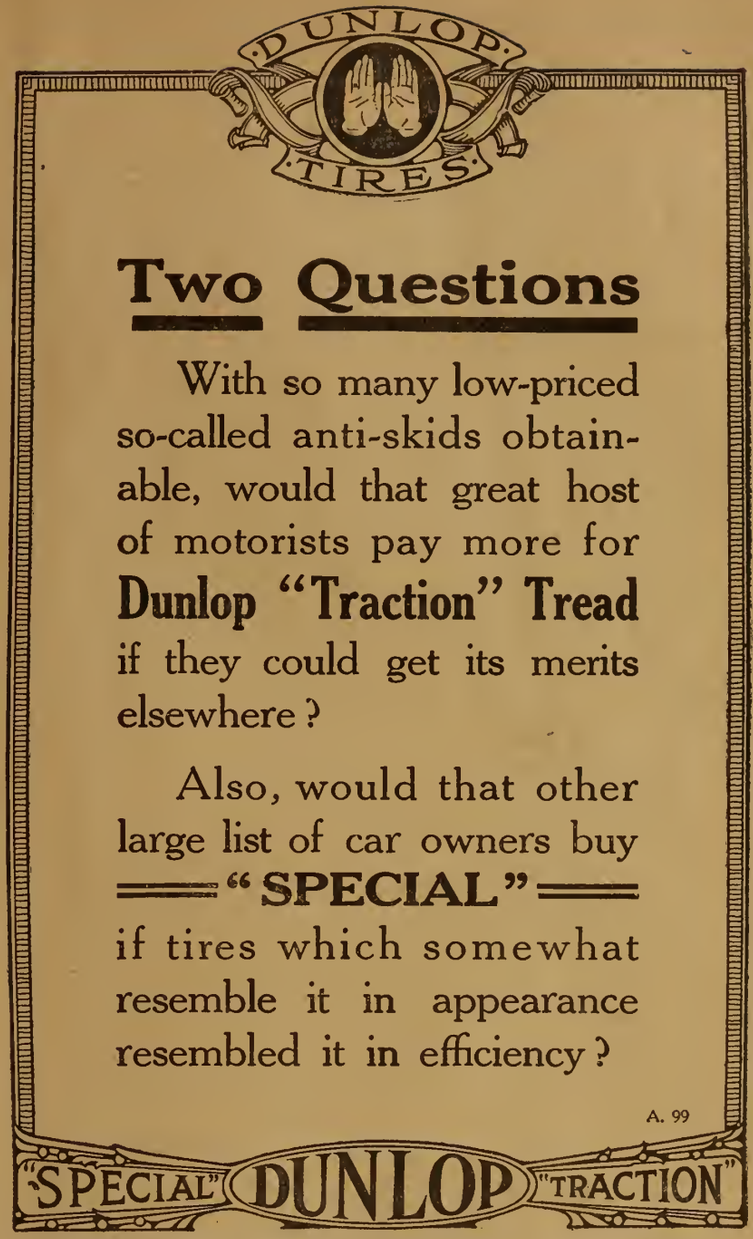
Then there are hundreds of horses that have shoulders that will never be fit to work until there has been an operation performed and part of the scar tissue cut away. Every time a shoulder is sore, in healing up there is bound to be some scar tissue formed the more the shoulder is affected, the more scar tissue is formed and in the end we have a great ill-shapen portion of esh and hide that is practically impossible for the horse to use in hauling and a sore shoulder is pretty likely to cause one or the other; a poor hauler or a poor disposition.

This condition can, in most cases, be greatly relieved by hardening a horse into the work. Usually one of the first jobs the team is put at is that of hauling manure, and if there is any heavier job than hauling a manure spreader in the early spring, I have yet to see it. The fact that the heavy hauling lasts for only a short while does not particularly alter the question. Blisters may be put on tender hands in ten minutes while if the same work was spread over two hours it would have not ecect whatever, so in hardening the horses into work it is better to give them light work for olng periods rather than severe work for short periods. Light work stretched over a week or ten days will usually put the teams in good condition for their spring's work. If this does not seem to harden the muscles rapidly enough, the shoulders may be bathed hemlock bark may be had. Good strong table te awill also do the same thing, or an alum water solution is often of value.

The collar that fits a horse is the most imperative of all. No amount of washing or hardening will make a misfitting collar fit. The collar should be of the right size and adjusted so that the point of draft will be just a little above the shoulder point. Pads on collars usually do but little good. When a rough plow handle blisters our hands we do no usually put on canvas gloevs. Rather, we get out the draw shave and some sandpaper and make the handles smoother. In this connection I have used the solid stove blacking to rub onto the wearing surfaces of the collars every morning to make them smoother.

Seldom as it is done, harnesses are made so they can be adjusted to the horse. It is easy to adjust the harness to the horse, but is much more difficult to adjust the horse to the harness as is so often tried. There is no excuse ofr the top of the head becoming sore through too tight a bridle. This often leads to poll evil. Neither is there any excuse for the crupper being so tight as to cause the horse to rise up behind in righteous indignation. The hames should also be adjusted to that the part where the hauling is done should be at or a trifle above the shoulder joint.

Not only does it conduce to the pleasure of driving a team to have them free from sores and blemishes, but it also keeps them more valuable in case a sale is to be made. If the harness is gone over carefully each spring to make sure that it fits the particular horse on which it will be used all summer, there is but little excuse for sore shoulders and sore necks.



DUNLOP
TIRES

"SPECIAL" DUNLOP "TRACTION"

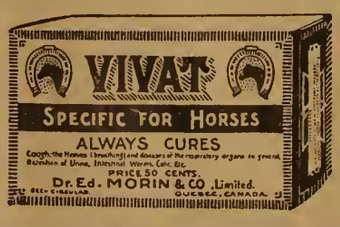
Harden off the shoulders by light work for a time and if this is not sufficient, bathe them once a day in some good muscle toughener. In addition to this careful driving and close watching will keep the team in A-1 condition, to the mutual profit of everybody cnocerned.—I. J. Matthews.

SUCCESSFUL PIE SOCIAL AT RENOVATING A BUGGY

Husbands who are not "Peter Tumbledowns" by any means often have too little pride in the up-keeping of buggies and harnesses, thereby detracting from the appearance of the fine teams which most of them possess. Years ago I began to look after the buggies, keeping them clean and painting them occasionally myself. Such work is neither hard nor disagreeable, but pleasant as outdoor work usually is. With an ordinary spray pump the mud can easily and quickly be rinsed off the wheels. Cleaning the carriage is no harder work than washing woodwork in the house. Clear water and plenty of it is all that is needed, no soap, of course.

When perfectly dry a coat of ready prepared carriage paint can be put on or thereabouts. No varnihsing or with an ordinary flat brush in an hour other treatment is necessary when this sort of paint is used. This year I put on new cushions which came ready to be tacked into place. I ordered them to fit by sending a pattern and measurements with the order. I also ordered a new top and dashboard at a total cost of $15. The buggy had looked old and dilapidated with its lack of paint, ragged cushions, its worn-out dashboard and sagging top, a discouraging subject for renovation certainly. However, the wheels, gear and box were good and with the fresh paint and new cushions, dash and top, it looks as good as new.

The Recognized Specific of Diseases of the Horse



A sovereign remedy in powder form which cures, Coughs, Heaves, Colic, etc. It strengthens the work horse as well as the race horse, and enables them to do more and better work. It has been successfully prescribed by many veterinarians notably by Dr. J. D. Duchene, in many critical cases, where results have proved remarkable.

A 50c box will be sufficient for six days' treatment.

DR. ED. MORIN & CO., LIMITED, - - Quebec, Canada

POULTRY.

FINISHING OFF POULTRY FLOCK FOR THE MARKET

There is something of a study about finishing off the flock of chickens to get the best out of them. We have three different classes of poultry products in that flock. The first to take our attention is the broilers, then the inferior pullets and cockerels that prove less valuable than we had expected when separating them from the broilers, and finally the pullets and cockerels we propose to keep.

As soon as the flock begins to develop feathers we will have to begin our study of their characteristics. Last year I picked out one cockerel that I planned to save, provided he showed no bad characteristics before he had half his feathers. He was so much larger than any other bird in the flock. Two or three pullets soon showed early maturity, and were chosen, subject to later developments. When the cockerels were of the broiler age my selected cockerel weighed ten ounces more than any other in the flock, and the pullets were not disappointing me. These were White Orpingtons, and all continued to show good points, but I have had Buff Orpingtons that would show up well at this stage and later show bad undercolor or black in the wings or tail, or some other bad feature that did not show at once.

Picking out the good ones.

One year we picked a fine buff pullet early, and she kept on developing as fine as she promised, and when she was a trifle over six months old she weighed seven and a quarter pounds, and was almost perfect in form and color. She began to lay early, and she kept it up, being one of the best layers we ever had in our flock. When all the pullets were fully developed many looked as fine as she did, but I would not have exchanged her as a breeder for any two of them. She had early maturity, heavy weight, good color held from the first, and splendid laying qualities, and we felt she would be likely to hand these characteristics down. If we had given little attention to the individuals of the flock early we would not have been able to distinguish her points. Early maturity is very important, and this feature can only be secured by close attention during growth.

When we have decided on what chicks we are going to market as broilers we should separate them at once and finish them off so they will bring the best price and come in on a high market. If we take these when they weigh about a pound and a half and shut them up we can put the other half pound on them in half the time we could do it with them running loose, and the gains will be made at less cost. Nor is this all. The time saved may make several cents difference in the price received. Quite often broilers drop a cent or two every day when the breaking point is reached. It will always pay to force broilers, for they will put on weight instead of growing in frame. If they are shut up where they get just enough exercise to keep them healthy, and get fattening food all they can eat. As they have little else to do but eat they do lots of that, and, so long as their digestion is good none of this food is wasted. It goes into fat and flesh. Plump broilers bring the top price, too.

When the pullets are finally selected which we want to keep, and the young cockerels selected also, we will bein to feed them for vigor and health with not so much attention to flesh or size. It is no benefit to give a hen over-development. If the size is shown during her early growth, and she matures early, she does not need to be forced any later. Let her range all she pleases, give her a well balanced ration, an never try to get her to eat more than she shows an inclination to eat. Let her develop normally. This same rule applies to the cockerels, though here we want to be on the lookotu for the least fault, for we do not want to breed from anything but the best, or sell inferior birds to others for breeding purposes.

It is the culls from the flock of pullets and cockerels that we saved for breeding purposes that stands to give us the most trouble and the least profit. They will not sell as broilers any more, and they will bring a low price as springers. Better than the part of the flock sold early, they will hardly bring us the profit these did. There is one market for these that will often save us and that is for breeding purposes to the farmer who is anxious to get better stock to mate with his ordinary mixed flock. Thees cockerels are fine, of course, or they would not be saved in the first place, and the small faults, which cause their rejection finally will not be an objection to many who keep pure-breds even, when they only want them for home use, and this market may take the supply at a fair profit. The cull pullets may be sold well for breeding, as they will be better than many a pure-bred flock iven ordinary selection, and a price secured that will give a profit on these. These are not stable markets, but still there is a good chance for them in any community.

L. H. COBB.

GAPES IN CHICKS PREVENTED BY EASY METHODS

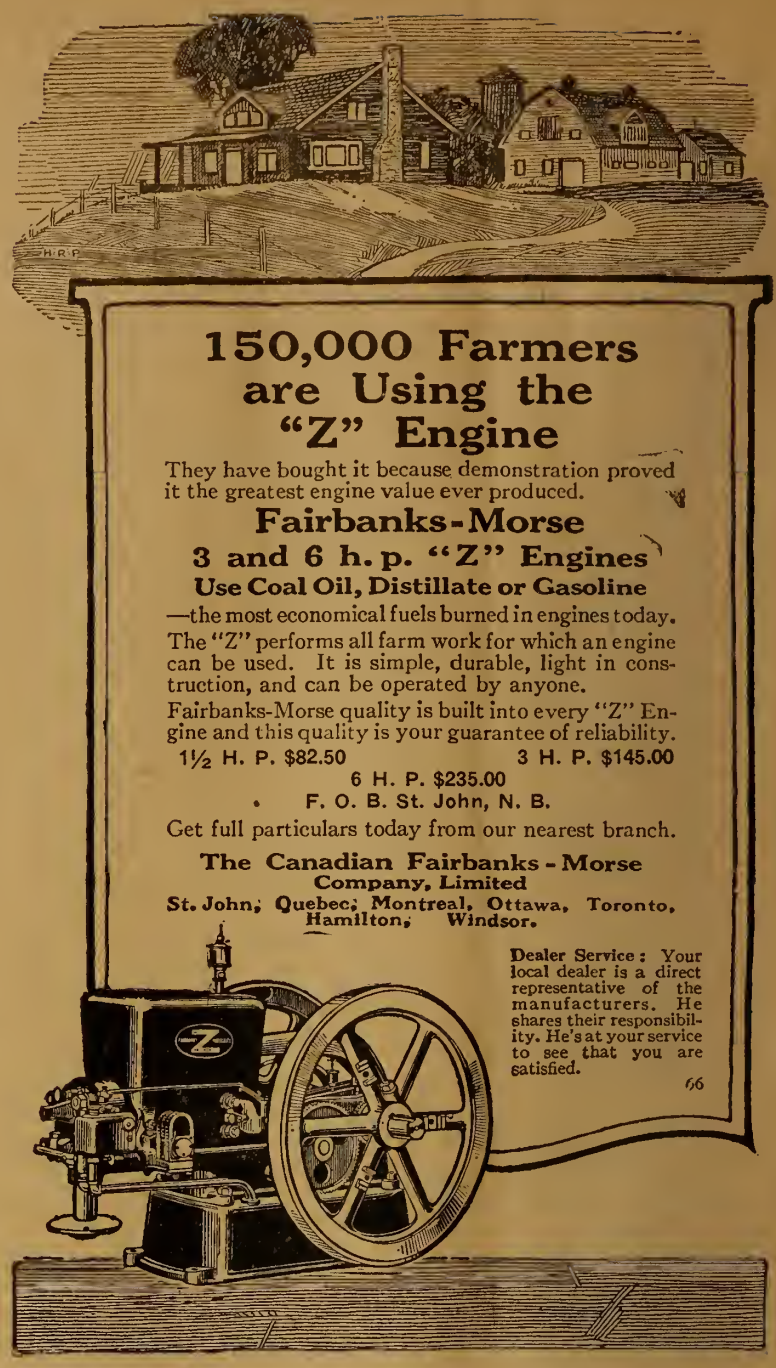
Gapes is easily prevented if a few simple conditions are met, but in sections where the disease is prevalent halfway measures will be of little value. It is most common on heavy soils, especially limestone, and practically unknown on sandy soil. The trouble is caused by small worms that get into the windpipe and cause death by suffocation. These worms are hatched from eggs of the mature gape worm, the eggs being picked up by the chicks and swallowed, when they soon hatch out in the digestive tract and make their way through the tissues of the body until they reach the inner surface of the windpipe, where they attach themselves. They grow to full size there, at which time they present the appearance familiar to every one who has used the horse-hair method of extracting them. At this stage the worms are mature and the females are filled with fertile eggs. When they are coughed up or the chick dies the worms also die, but the eggs stay in the ground until the next season, if they are not picked up before. It is believed that the common earthworm or "fishing worm" is the chief means of conveying the eggs from the soil to the chicks.

It should be clear from this that the way to prevent gapes is to keep the chicks away from infected soil. Burning the dead ones is good; sprinkling the ground, especially all bare spots, with air-slaked lime also is good; keeping the coops and runs clean and sweet is important; but the only way entirely to prevent gapes is to keep the chicks away from infection.

There are two practical ways of doing this. The cheaper and better one is to have two yards of nursery plots of sufficient size on which the chicks can be brooded on alternate years, the vacant yard being devoted to some crop—grass is best, as it leaves a sod for the chicks to run on. During the off year this yard must not be used for poultry at any time—either young or old. If this is done there will be practically no infection the second year, chicks can be raised alternately on these two plots with practically no losses from gapes. After the chicks are four or five weeks old they may be allowed to run at large, as they will then be safe from infection, or if infected they will be strong enough to cough up the worms and will not be injured by them.

The other way is to confine the chicks continuously indoors until they are four or five weeks old. A permanent brooder house where they will be comfortable and will have plenty of room is bets for this, but many farmers are able to utilize an empty mow or some vacant building of sufficient size, and wtih proper care and feeding can do this with entire success. The only essential is to keep the chicks away from the infected soil and where they will have no opportunity to pick up worms until they are old enough to throw off infection.

Where it is impossible to do either of these things, the next best plan is to confine the chicks to a comparatively small yard and use air-slaked lime lavishly, raking it into the soil so as to avoid injury to the tender feet of the chicks. Do this not once but several times during the breeding season. This will very materially reduce losses. When chicks have gapes many can be saved by the use of a twisted horsehair or better still a wire gape extractor, such as can be secured from almost any poultry supply dealer. There are various advertised remedies that are more or less effective.



150,000 Farmers are Using the "Z" Engine

They have bought it because demonstration proved it the greatest engine value ever produced.

HOME-GROWN GRAIN FOR POULTRY

Feed is high and hard to obtain. The Allies are depending on the west for their grain supply. Let the poultryman do his bit by helping out the feed situation and raising at least his scratch grain in 1918 on his own farm. Be self-supporting, don't be a dependent. Raise poultry in 1918. Plant grain this spring to feed them. Help transportation conditions out by raising grain on the farm.

It is cheaper to raise our grains on the farm at the present high prices than it is to buy them from the west. The following grains are used in varying proportions in scratch grains for hens and chickens, and can all be profitably grown. Corn, oats, barley and buckwheat—this is a practical and businesslike proposition. If you don't think so, look over the figures you find listed below.

Some average figures on yields per acre and cost per bushel, taken from farm accounts of Maine farmers from all parts of the state:

	Yield in bu. per acre	Cost per bu.
Corn	53.60	$1.62
Oats	31.11	.85
Barley	20.30	1.70
Buckwheat	14.00	1.86

The last three grains listed also furnish a large amount of valuable straw that can be used for litter.

Compare these figures with the prices you are paying now at the grain dealer's. Subtract the value of your straw and the cost of hauling your grain from the dealer's to your farm. You will find a very favorable balance on the side of the home-grown scratch grains, I feel sure.

Barley, oats and buckwheat can be grown on every farm. An excellent scratch grain can be mixed from the above grains. For example: 100 lbs. barley, 100 lbs. cr. corn, 100 lbs. oats, or 100 lbs. cr. corn plus 100 lbs. oats, or 100 lbs. oats plus 100 lbs. barley, plus 50 lbs. buckwheat, etc. Decide now, poultrymen, what your scratch

grain will be for next year, and plan your grain acreage accordingly. Remember that you are feeding by weight nearly equal parts of scratch grain and mash. If you raise one-half of your hens' feed on the scratch grain, you will be doing a big bit to help out the feed situation.

Poultry is a necessity on the farm, eggs are the highest even known, poultry meat is high. Farmers must maintain poultry production by raising home-grown scratch grains. Remember, food wins the war. Do your part.

John S. Carver, Poultry Specialist.

HEAD LICE IN CHICKENS

The chicks sould be gone over for lice—the head lice are the worst. If the brooder and the surroundings are kept clean as possible there should not be much fear of head lice. Should they appear, however, an application of ointment of some kind should be used at once. If this is not available, use vaseline, olive oil or sulphur and lard. Every head will have to be gone over and treatment will have to be repeated in a week. . tI is a troublesome task to go over several hundred young chicks, but it must be done, each head by itself. Rub the paste well into the scalp and around the ears. Some use coal oil, but it is too severe and has been known to kill the chicks about as quickly as lice. Head lice are hard to locate in chicks sometimes. The chicks may be listless, getting thin, wings down, feathers ruffled, and dying off one by one. Upon examining the heads one can see nothing running around and all that appears is what looks like young feathers sprouting out of the head. To make sure that they are there, take some of the ointment and aply thoroughly to the head. Put the chick in a box and examine in a few minutes time. The young feathers will be gone and large bodied lice will be running for their lives. The feathers were abdomens of the lice, the head and the rest of the bodies being buried into the head of the chick eating away at the tissue. It takes only a few days to have a whole flock cleaned out. Absolute cleanliness is the best preventative.

WHY CHICKS DIE IN THE REARING

The life of the chick is dependent upon the parent stock as well as upon the method of incubation, and finally upon the method if brooding. A fine lot of vigorous chicks may be hatched from eggs from the best stock, and through improper methods of brooding totally unsatisfactory results may be secured.

The main thing in brooding is the temperature. Little chicks three or four days old are fairly hardy creatures, but when placed under extreme conditions weakness or death is sure to follow. The chick's lungs are situated along the spinal column, and are protected only by a thin membranous lining over which a light covering of feathers grow. Provided with such meagre protection the lungs may become readily chilled or overheated. An even temperature in the brooder, with as little variation as possible, is most desirable.

The brooder should be started a day or two before the chicks are to be placed in it, so that an even temperature of about 98 degrees may be maintained. This temperature should be gradually lowered, and it depends upon the season of the year just how much it should be lowered. The poultryman must use his own judgment and operate the brooder according to the condition of the chicks.

Another problem second in importance to temperature is that of foods and feeding. Just as the little chick is hatched, the remains of the yolk are withdrawn bodily into the cavity. The food contained in this absorbed yolk-sac provides for the chick's sustenance unti lit is able to obtsin food by its own efforts. It is due to this provision that it is not wise to give it any food for about fifty hours.—M. A. JULL, Macdonald College.

REARING CHICKS TO VIGOROUS HEALTH

The perid of brooding chicks with hens or with artificial brooders depends upon the season of the year. In the early season, or if it is cold or damp dufring the normal brooding season, the chicks will re quire to be brooded for a longer time than under normal conditions, which usually lasts from eight to ten weeks.

The direct object in the treatment of the growing stock is to promote normal growth. Uniform development is necessary to insure satisfactory results. Chicks of the same breed vary greatly in size and vitality and it is wise to kill off all weaklings at hatching time. As the chicks develop, the weaker ones should be eliminated from the flock. A rigid system of selection should be carried out from hatching time to maturity and all chicks lacking in vigor should be killed. A good time to weed out the weaker chicks is when they are about eight or ten weeks old. These should b eplaced by themselves and in some cases can be fattened profitably. With the rest of the flock the aim should be to keep them in the best possible state of health and growth.

To thrive well they must be given plenty of range on clean soil. As for as possible, avoid raising the chicks on the same ground year after year, since the land on which chicks are raised continually without cultivation soon becomes dirty and is liable to cause sickness and disease among the ffocks.

Overcrowding the chicks on a small are a of land will cause much trouble during the growing period. Plenty of range tends to make the chicks more vigorous and will lessen the cost of feeding. Where the chicks are allowed to run in the orchard or cultivated fields on the farm they are able to feen on many worms, insects and other material. They will also get plenty of green food which is so esential in the successful raising of chicks. The cultivation of land on which the chicks are being raised tends to keep the soil sweet and clean. Chicks on free range can obtain much mineral food wihch assists greatly in their proper development.

Growing chicks require plenty of shade. The orchard will supply plenty, or if the orchard is not available the chicks should be raised on land where crops are grown. The corn field makes one of the best places for the young stock. —M. A. JULL.

POULTRY POINTERS

A young turkey is like a cat; its power of recuperation is remarkable. You are never sure that it is dead. They can often be picked up to all purposes cold, inert corpses, and held in the hands and warmed, and then comes a gasp and a return to life, and the bird is quite ready for brakfast the next morning.

There is little use trying to keep turkey chicks on a limited range. They love to walk and also to roost in the open. The turkey hen is an ideal sitter, but a bad mother unless confined, as she drags her young after her, and does not wait for those that fal out by the way so long as one is left.

Growing ducklings thrive best on a feed composed of equal parts, by measure, of corn meal, ground peas, bran and middlings, all made into a thick mash, either with scalding hot water or milk, the latter being the best. The mash is improved by adding short-cut green stuff, and a few handfuls of coarse sand.

ONE CENT WILL SAVE ME

That's all it costs for three weeks'-feeding with

Pratts Baby Chick Food

The young chick needs a scientifically prepared food. It cannot digest vegetable fibre. It must have phosphate of lime and other bone and muscle builders. How's it going to get them? GET THEE BEHIND ME, SATAN!

(Continued from last issue.)

"And shame the devil," said the little manager. There were tears of sympathy and understanding in her blue eyes.

She helped Miss Cornelia to her feet, but Miss Cornelia suddenly gasped and sank backward—

"The—matron!" she whispered, and her face, with terrified eyes, was turned to the door.

Outlined against the distant hall stood the manager in blue, her eyes hard and unforgiving, and by her side in her new black silk with the white ruche about her thin throat stood the matron, weary, miserable with headache written in little lines of pain above her bent brows. Her glance, traveling down the crowded room, found Miss Cornelia. Impressively she made her way toward her. When she got within speaking distance, she stopped, lifting a thin, nervous hand—

"Miss Cornelia," she said heavily, "I have been most surpricsed and pained by your actions—we will not discuss the matter—you will kindly return to your room." She swept her pained glance about among the guests as if here were a sample of what she bore with a martyr's fortitude, for fifty-two weeks in the lagging year!

Miss Cornelia for just a moment went blind. She rose to her feet, staggering a little, and tried to speak, but her tongue clove to the roof of her mouth—Miss Cornlia, deserted at last by even the Evil One, could not utter a word! And then slowly, guided by some one, she went down the long flower-decked room, past the table with its blurred glitter of cnadles, past the Paris gowns, that looked like ghosts with the bodies missing, past the gold lorgnettes, and the frigid shocked faces, straight to the green baize doors. It was Miss Cornelia's way of crucifixion, and she walked with a little prayer on her lips, for Miss Cornelia had said good-by to the Evil One forever!

I think, between you and me, he was sorry to say good-by to Miss Cornelia. You see, he knew at that very moment that two irate old women were waiting before Miss Cornelia's locked door—he wanted to see just what they would say when she appeared in the clothes she had no right to—the real lace jabot and the plum-satin gown! So he raced ahead of Miss Cornelia and found a place to hide in, in other words, he glared out at her from Widow Brown's cold eyes.

"So deceitful," she began as the culprit came nearer, "co awful common and bold—to go down decked in other folks' finery and we trusting you with the best we had on earth! Just look at the creases where you sat on it—and dribbles of ice cream on that tucked breadth. My lands, I call it being a whited sepulcher—singing hymns in chapel on Sunday, and consorting with the devil the rest of the week!" By this time the widow's fluency gave out and Mrs. Parker took up the theme.

"My goodness, Cornelia—you gave me a turn, you did! I suppose you put pin marks all thro' that lace! And talking about your cotton crochet! I should think you'd be ashamed to tell lies like that at your time of life!"

"I am ashamed!" quivered Miss Cornelia.

"And dangling about in Nancy Huggins's earrings—if I was Mis' Huggins I'd cut you dead, that I would and feel no sualms to my conscience!"

Miss Cornelia clasped her trembling hands together. "I'm sorry," she murmured, "oh, I' msorry—"

"And the Lord don't ask no more of us, Cornelia," said some one cheerfully. It was Nancy Huggins coming down the corridor.

Don't speak to her—the deceitful wretch," gasped the widow. "Look at her! wearing your carnelians as if htey'd been handed down in the family! And strutting about among the lady-managers, while the rest of us were cooped up here doing our dooty. Don't tell me that Satan han't got into her!"

Nancy Huggins looked serenely at the Widow Brown's darting eyes. "Well," she said, "Mis' Brown, we all know he goeth about as a roaring lion devouring his prey, and I will say I've met him right here, in this corridor, and one of the first signs of him," said Nancy evenly, "is a hasty tongue. You just count twenty before you say another word to Cornelia, and I bet it will be a kind one. As for Cornelia—I'm not upholding wrongdoing, but from the look of her, she didn't have a good time while she was doing it—she's clean tuckered out. I think," said Nancy wisely, "we're all of us too near the borderland to squabble. As for scolding—the Lord has his own way of doing that, he don't need your tongue or mine to help him! Now you come along with me, Cornelia, and I'll help you get off that toggery. No—Mis' Brown—you better stay outside, I'll hand 'em to you through the door." Miss Cornelia, like a little child, followed her.

The stately person tapped with her gold lorgnette upon the back of the secretary's chair. "It is very distressing," she said, "but there seems to be only one course open to us!"

The matron, still bearing traces of headache, stood facing the Board. They were in the managers' room, three days later, and the green baize days were closed. "I hope," she said miserably, "the ladies uphold my attitude. I have tried to be disciplinary, not severe. I have kept her in her room and denied her desserts and visitors until your honorable Board should come to some decision."

The president bowed. "Certainly, Mrs. Marter—we understand exactly. Your position is bound—ahem—at times to be trying. The whole affair is very distressing."

A youthful-looking manager in a ragish little hat twined with roses, smiled broadly. "It's distressingly funny, I think," she said.

"To think," murmured the stately person "that we were all so taken in. So very mortifying! Miss Twitchell, indeed—we might have realized she wouldn't have come in such an antediluvian get-up!" Here the stately person actually snorted.

The matron put one blue-veined hand to her brow and kept it there.

The president rose. "That will do Mrs Marter, thank you" The Board will act at once" She opened her watch—"In ten minutes please see that the inmate is sent here to us."

A manager at the end put a question. "Just how," she asked nervously, "will we put it?"

"As briefly as possible. There are only two courses open to us. Retention with reprimand, or expulsion."

"Oh," murmured the soft-hearted manager. She had peen biting the end of her pencil for the last five minutes. Suddenly she rose. "If I am not interrupting the Board," she said hurriedly, "I would like to say a word. We must remember that they are just dear old babies, all of them, and you can't scold babies the way you can other folks—I know, because I've two of my own at home. Besides, she told us several things that were true. Of course I know we couldn't provide pocket money and things like that, but I want to say—" here she blushed vividly, "I want to say that Teddy, my husband, I mean—gave me a hundred-dollar check for the Home this morning and we both wish it to be used for ice cream on Sundays as long as it will last!"

There was a distinct silence. The president, broke it. "That is very sweet of you, Mrs. Foster, very—and I think, although it seems like putting a premium on—on crime, that the Board will not object. Personally, I think ice cream is harmful to old stomachs and we need new hymn books in the chapel, but as it is your gift, of courseJ"

"It is Teddy's gift," said the little manager bravely, "and it for ice cream—nothing else."

The president flushed. "We will proceed to the matter in hand," she said shortly. "'Ladies, will you vote at once?"

The secretary counted the votes. "There are seventeen," she said, "for expulsion—the majority by one."

"Oh—" whispered the soft-hearted manager, and subsided mournfully into her seat, while her eyes did a rapid counting.

It was just here that the doors swung wide to admit a white-faced, frightened little old lady with red-rimmed eyes who stumbled as she crossed the threshold. Her eyes, traveling pitiously around the room fuond the manager with the soft heart and rested there.

There was a pause. The president, rising, spoke slowly. "It grives us very much," she said, "I speak in the name of the whole Board, to have to communicate to you our painful decision. We try to make our Home a pleansant one, but it is established upon rock-bound rules, and principles of honor and rectitude. Your defection has been so great—that we feel it necessary to make an example to others—to, in fact, to send you from us, Miss Cornlia.

Miss Cornelia swayed a little. She wondered why the room persisted in turning around, and why the light of the windows shifted so—

Suddenly the soft-hearted manager frowned and found her clearest, most

bell-like voice. She leaned forward a little. "Excuse me," she said very distinctly, "excuse me Madame President, but the secretary has dropped two papers. One of them is under the table—the other is here by my chair."

The secretary stared, stooped, fumbled. "Very careless," she murmured, "I have on my wrong glasses—I didn't see. Yes, two votes. This makes, I find, a—a difference—if you will allow me to count again."

She laid them separately out upon the table, while the soft-hearted manager waited, tapping her little foot on the floor. The secretry looked up with flushed cheeks. She must either accuse a member of the Board of—of cheating, or accept the altered verdict. She decided to accept the verdict. Only she knew what nobody else would dream of—that the manager with the soft heart had voted three times!

"As it stands now," she said steadily—it is retention—with reprimand."

"Miss Cornelia," said the president, it seems you are to stay with us a little longer. Have you anything to say?"

Miss Cornelia made a little movement forward her eyes were swimming with tears. She clasped her hands together in the old childish fashion.

"Only that I am glad," she said, "because it is—my home!"

Miss Cornelia turned her blue eyes timidly on the sea of faces; it was surprising how, all in a minute, they had grown kind. Some of them were tear-wet, like her own, some of them were smiling, but out of them all the face of the little manager shone brightest, and Miss Cornelia, watching her intently, suddenly knew why.

THE CHILD'S EARS

(By Gertrude Crownfield)

A deaf child is a most pathetic little creature. If his defect is not discovered early, he is apt to be misunderstood and blamed for inattention, disobedience, and stupidity at home and at school.

Much can be done to prevent deafness, if done in time.

Earache is usually the first danger signal.

Many parents accept it as an almost necessary evil. On the contrary, an attack of earache should arouse instant attention.

A stopped or "queer" feeling in the ears is just as dangerous as pain, for it shows a blocking of the Eustachian tube that lead from the throat to the inner ear.

Often, children, too young to speak, will whine when the ears are touched, put the hand to the ear in a nervous way, or roll the head from side to side as if uneasy.

Sometimes the child will be cross and fretful for several days, when suddenly there will be a flow of pus or watery fluid from the ear, showing that there has been inflammation of the middle ear, with perforation of the drum membrane. Such perforations often heal; but if the cause of the inflammation is not discovered and removed the condition may become chronic, or other acute attacks may follow, the drum may thicken, and in time the child may become partly if not totally deaf.

It is always a suspicious sign to see a child turn one ear more frequently than the other to the speaker. Every child's hearing should be tested now and then by speaking to him from an adjoining room, from back of him, and from the side, at a reasonable distance from him, and using an ordinary tone of voice, saying something that you are sure he would like to hear.

Middle-ear inflammation is at the root of most cases of deafness. It may come from various causes, among which are scarlet fever, influenza, measles, whooping-cough, diptheria, mumps, typhoid fever, injuries to the ear, bad teeth, adenoids and tonsils.

Violent coughing or vomiting in whooping-cough may rupture the ear-drum, or drive infectious germs, or even food, into the middle ear, and set up serious inflammation there. it may also give rise to hemmorrhage in the ear. An attack of pain in the ear during whooping-cough requires the prompt attention of a physician.

Adenoids should be removed, and swollen tonsils attended to, because they keep up a constant irritation and inflammation of the mucous membrane of the nose and throat which spreads to the ear.

The same condition arises from coughs and colds; and a child suffering from either needs to be taught not to sneeze or cough violently, or more often than can be avoided. Teach him to blow his nose gently with both nostrils open. Nasal douches are dangerous, and should never be used.

Surf beating on the ears, ducking or diving, has sometimes broken the ear drum, or if it was alreday ruptured, it lets the salt water directly into the inner ear, which is apt to become infected by it.

Never box or pull a child's ears in play or as a punishment.

There is a great danger of middle-ear inflammation extending to the surrounding parts, producing mastoiditis, meningitis, or brain abscess; or a general poisoning may take place from the pus being absorbed into the system.

A hot-water bag, salt bag, or hop pillow, furnishing dry heat, are the only means that should be employed

WEAK AND NERVOUS

AFTER

SERIOUS OPERATION.

After any serious operation or sickness, the nervous system is generally left in an extremely weakened condition, and a course of Milburn's Heart and Nerve Pills will do more towards building it up than anything else.

Mr. W. E. Grafton, 44 Davenport Road, Toronto, Ont., writes: "My wife underwent a very serious operation three years ago. After leaving the Toronto General Hospital she was in a weak, nervous condition. Having tried numerous medicines, from which she received practically no satisfaction, I decided to try Milburn's Heart and Nerve Pills. I am very pleased to say that they proved very satisfactory. She slept and ate well, and her whole physical condition improved wonderfully. I have always kept a box in the house, and find them very useful in cases of nervousness, sleeplessness and fatigue."

Milburn's Heart and Nerve Pills are 50c. a box at all dealers or mailed direct on receipt of price by The T. Milburn Co., Limited, Toronto, Ont.

to relieve pain in the ear. Be sure that these bags are not so full as to be hard to the ear. Drops of all kinds, poultices, and all moist applications should be shunned.

If there is a discharge from the ears and the doctor orders it to be irrigated with a fountain syringe, be sure that the bag is suspended not more than two feet above the ear, to that the fluid may flow in very gently. Hold the nozzle one-quarter to one-half an inch from the ear opening, so that the fluid may have a proper chance to return; otherwise it may do harm.

For several weeks after an attack of middle-ear inflammation, extra caution must be used about exposing the child to the weather, or allowing him to become overtired. If his ears are at all sensitive, bits of cotton should be placed in his ears before going out.

If beans, peas, seeds, beads or other objects get into the ear, do not make frantic efforts to get them out. No harm will be done by leaving them in for some hours, or even days, if necessary, in order to get a doctor. Almost without exception the real damage is done by unskilled efforts to pry out the objects.

The end of the towel must not be rolled into a hard point to dig out dirt and wax from the ear canal. Wax is especially provided to keep the inside of the ear canal and the drum in good condition. It is in no sense dirt, and only so much of it should be washed away as rolls into the outer ear, and can easily be removed by a damp cloth stretched over the tip of the little finger.

If insects fly into the ear canal, a drop or two of sweet oil will smother them at once, and they can then be removed by gently syringing the ear with a mildly warm boric acid solution —two teasponnfuls of boric acid powder dissolved in a half-glassful of warm water. Use a syringe with a tip too large to enter the ear canal and hold one-quarter of an inch from the ear opening. Never use picks or pincers to extract anything from the ears.

In case the child becomes deaf, and the specialist is unable to restore the hearing, the question of having him educated in an institution for the deaf should at once be carefully considered.

In such a school the child is given a good general education, is taught a trade at which a deaf person can easily support himself, and special care is given to retain what ability the child has to talk (and a child whose hearing is seriously impaired will certainly forget how to talk.)

In addition, the child, if bright and intelligent, will be taught lip-reading. It is remarkable how many deaf people there are who can carry on a conversation by means of this art.

The younger the child begins this training the more thoroughly will he master the details of it.

Had Piles For Ten Years

And Tried Nearly Everything Except a Surgical Operation Without Obtaining Relief. — Tells How Complete Cure Was Effected

There are reported here three cures of chronic cases of piles. In all three cases many treatments were tried before it was discovered that Dr. Chase's Ointment is about the only real cure for this distressing ailment.

Mrs. A. Oates, 22 Gilkinson street, Brantford, Ont., writes: "I have used Dr. Chase's Ointment as a household remedy for ever so long, and am particularly indebted to it for a cure from Piles. I had suffered from this annoying trouble for ten years, and tried nearly everything I heard of. After using Dr. Chase's Ointment a short while I was completely cured."

Mrs. Wm. Shantz, 155 Albert street, Kitchener, Ont., writes: "For several years I was troubled with bleeding piles. I tried different remedies for relief without success. I read in Dr. Chase's Almanac of the benefits other people were receiving from Dr. Chase's Ointment, so Isent to your office for a sample box. I found it gave me such relief that I went to a drug-store and purchased a full sized box. I have used several boxes since and have derived more benefit from its use than any remedy I have ever used.

Mrs. F. Cussons, Victoria street, Ingersol, Ont., wirtes: "About two years and a half ago I was suffering from Piles. I had tried many different remedies for this distressing trouble, but nothing helped me. Finally I got a box of Dr. Chase's Ointment, and after using it found that I was completely cured and have not been bothered in this way since. I can cheerfully recommend Dr. Chase's Ointment to anyone suffering as I did."

Dr. Chase's Ointment, 60 cents a box, at all dealers or Edmanson, Bates & Co., Limited, Toronto. There are no rivals to Dr. Chase's Ointment as a treatment for Piles.

CHEESE INSTEAD OF MEAT

Cheese is a neglected article of diet, declare nutrition experts of the Department of Agriculture. As a rule, it is more often used as a mere appetizer than as a major article of diet. A pound of cheese, experts declare, supplies more than twice as much energy as a pound of fowl or roundsteak, and almost twice as much protein as the same amount of fowl or ham. Cheese therefore, it is pointed out, is an economical and satisfactory meat substitute.

Mayor Mitchell said at a dinner in New York:

"Insurance rates, now that we're at war, will naturally go up. I heard the other day about a young fellow who went to an insurance agent and said:

" 'I' dlike to take out a policy, please.'

" 'Very good, sir' said the agent. 'Sit down and have a cigar. Now then, what kind of a policy do you want to take out—life, fire, burgulary, accident, murder, drowning, assassination or marine '

" 'I'll take the whole caboodle of them.' said the young man. I,m going to try to cross to England through the U-boat blockade.' "

DRIED PEACH CUSTARD PIE

1 Cupful Dried Peaches, Cooked
Sugar to Taste
Rind and Juice of 1 Lemon
2 Eggs
Cinnamon or Nutmeg.

Stew the peaches and mash to a pulp. To one cup of peaches add the well-beaten egg yolks. Sweeten and add a pinch of cinnamon and a dash of nutmeg; lastly, grate the rind of the lemon into the mixture. Squeeze half of the juice into the custard, saving the other half for the meringue, which is addcd after the mixture has been allowed to cook for a few minutes to set.

This same recipe is excellent for dried apple custard, or to use for fresh apples. With the apples, substitute vanilla flavoring for the lemon. Dried fruits make better custards than fresh, and the dried fruits need much less sugar. In fact some dried fruits require no sugar at all.

SYMPATHY WITH CHILDISH SORROW

There are many mothers who do not realize how real is the grief of a child. If a little one breaks a toy and comes to you with tearful eyes and quivering lips to tell of the loss, do not turn away carelessly or impatiently, but speak some comforting word, for the little heart is aching over the loss of this cherished plaything, and the sorrow is just as genuine as any you have felt.

The little one has come to you for comforting cheer in this hour of childish sorrow, and if you would retain its confidence, heed these little things which are big things to your child, so that in later years when real sorrow may come into his life, he will turn naturally to mother for help and comfort. Your child turns to you as naturally for sympathy in joy and grief as does the flower to the sun; then see that in return you give your sympathy and help, or in after years this child, to boyhood or girlhood grown, will go to another for what you have failed to supply. Can you trust anyone else with that child's interest and welfare? It is yours, placed in your hands to rear for weal or woe. No one can understand your child as you should be able to, for no one has made of its life and temperament a study as you have or should have done. Keep this confidence of your child, as you have its best interests at heart. If it does not come to you with its little pleasures and griefs, its childish secrets, be sure there is something wrong, and in yourelf. Find where and in what you have failed, and set it right at once while you can, or some day you may be sorrq. Your child will know in its heart that mother has failed him. Think what that means to you—failure as a mother. Is there any trouble too great to prevent this happening? Is the keeping of your house, society, or anything more important to you than being a good mother? Do not for peace of mind's sake in later years, let anything come between you and your duty to your child.

HOW TO MAKE HOME ATTRACTIVE

There is such a thing as throwing around the home so many beautiful things. I do not mean beautiful in art to catch the eye, but beautiful in thought and association as to hold the heart, that children will cling to it with undying love.

The complaint is often made by parents that as soon as their children become old enough to mingle in society, their home is forsaken. They become uneasy and restless when compeled to remain even for a single evening in the home, and almost any other place seems to be preferred to that where father, mother, brothers and sisters are found.

This complaint is made with a tone of deep regret, but at the same time perhaps, the parents who make it have no suspicions that, after all, the cause of what they depricate is found in themselves. "Diving and finding no pearls in the sea, blame not the ocean, the fault lies in thee."

No child, however sentimental, will love a home simply because it has the nome of one. If we would have our children love it, we must make it lovely; we must give them something to love in the home.

Now if the principal ideas which a child has of its home are that it is a place where to get his meals, where to sleep; where if he is little he is perpetually found fault with; where he must be quiet; where at nightfall he must sit stupidly waiting 'till bed time ; or if he has grown older he can only deem it a dreary room in which he must employ himself as best he may, while the father sits at his paper or doses in his chair, and the mother is silently busy with her sowing or her book. If such be the aspect of home, one need not wonder that children learn to look elsewhere for pleasure, and seek to find amusement in theatres and questionable places.

Let the table be the happy meeting place of a merry group and not a dull board where a silent, if not sullen, company of animals come to food; let the meal be the time when a cheerful laugh is heard, and good things are said; let the sitting room at evening be the place where a smiling company settle themselves to books or games 'till the round of goon night kisses is in order.

Let there be some music in the household; music not kept like silks and satins to show to company, but music in which father, mother, sister and brother can join.

Let young companions be welcomed and made for the time a part of the group, so that daughter sshall not deem it necessary to seek the obscurity of back parlors with intimate friends, or to drive father and mother to distant apartments.

In a word let the home be surrounded by an air of cosy and cheerful goodwill; then, children will not be exhorted to love it—you wil not be able to tempt them away from it.

SKIM MILK'S VALUE AS HUMAN FOOD

Skim milk has been looked upon as an inferior article of human food and has been mostly used as a food for stock. It is without question a most valuable food for young pigs and calves, and is abolutely necessary for their growth and development. There, is, however, a large amount of skim milk fed to mature hogs which could be used to advantage as human food.

Skim milk contains practically all of the constituents of whole milk, except the butterfat. It contains the sugar, the protein, the albumen and the mineral matter, also the substance called vitamines, which has been found to be absolutely necessary to the growth and health of the human body.

tI is not the aim of this article to advise the substituting of skim milk for whole milk, for we all know that the butterfat is the most valuable part of the milk, but the skim milk will do just as well in the making of batters for bread substitutes and where there is a sortage of whole milk. It might be well during this time of food conservation, for people to make a more general use of skim milk in the home.

At the Yarmouth Y. M. C. A. Boys' Camp, held at Tusket Falls in August, I found MINARD'S LINIMENT most beneficial for sun burn, an immediate relief for colic and toothache.

ALFRED STOKES,
General Sec'y.

RINKTUM DITTY

4 tbsp. flour.
2 tbsp. fat.
1 cup tomato juice or mik.
1 cup milk.
1½ cup cottage cheese.
1 egg if main dish at meal.

Make a white sauce of flour, fat, milk and tomato juice and stir in the cottage cheese or American cheese. Serve on toast or wafers for lunhceon or supper.

SAUSAGE

part lean beef.
1 oz. salt.
2 parts pork.
1 oz. pepper.

Sprinkle seasonings over meat and put through food chopper. The amount of seasonings give nabove are for four pounds of meat. If the meat is packed in muslin bags and hung in a cool dry place it will keep for a long time.

CORN FRITTERS

To one can of corn add 2 eggs well beaten, 2 tbsp. flour, 1 tsp. salt, ½ tsp. pepper. Mix thoroughly. Have pan hot, grease with 2 tbsp. lard, and drop the mixture in spoonfuls. Brown, turn, serve hot.

PASTRY

1 c. middlings.
¼ tsp. salt.
4 tsp. butter
½ c. pastry flour.
4tbsp. lard.
Water.

Sift flour and salt, cut in lard, add cold water. Roll out mixture and add butter in small pieces. Fold and roll. This amont is sufficient for two shells.

RAISIN PIE

2 tbsp. flour.
1 c. water.
¾ c. sugar.
1 c. raisins.
Juice and grated rind of one lemon.

Mix sugar and flour, add water, lemon rind and raisins. Cook. Add juice of lemon This may be baked in crust with strip across top or put filling in baked crust, dot with meringue. Decorate with plump raisins.

KOL DORMER

Grind 2 lbs. steak or cheaper meat through food chopper with 2 slices salt pork; add 1 c. boiled rice; ½ c. milk, 1 tsp. salt, pepper. Chop 1 onion and brown it lightly in 2 tbsp. drippings. Add to the meat, mix together and make into little rolls 4 in. long and 2 in. thick. Take as many cabbage leaves as rolls, drop them into a pan of boiling water and let stand until they are wilted. Place roll of meat on leaf, roll up and tuck in ends neatly. Lay in greased baking pan, cover closely and bake in moderate oven 40 min., basting frequently. Serve hot.

STEWED POTATOES

6 potatoes.
3 tbsp. butter.
Water.
Salt and pepper.

Wash and pare potatoes, slice, cook until tender, let water simmer away. Season with salt, pepper and buttter. This is a quick way of cooking potatoes. Onion may be cooked with potatoes.

WAR-TIME BREAD PUDDING

¾ cupful Corn Sirup or Brown Sugar
Grated rind ½ orange.
1 cupful ground bread crumbs.
½ teaspoonful salt.
1cupufl boiling water.
½ cupful raisins.
1/3 cupful shredded dates.
3 cupful milk.

Pour the boiling water over the crumbe. Combine the other ingredients and bake in a buttered dish an hour in a moderate oven. Honey or maple sirup may replace the corn sirup.

They all come out of the "BEAVER" FLOUR Barrel
Apple Pie and Hot Rolls for supper—Jelly Roll and Chocolate Cake and delicious homemade Bread for dinner —Puddings and Doughnuts, and Cookies and Raisin Bread — all at their daintiest and best when made of
BEAVER FLOUR
T.H. TAYLOR CO.
BEAVER FLOUR
MILLED OF BLENDED WHEAT
"Beaver" Flour is just as good for Pastry as for Bread. It is the product of Ontario winter wheat, blended with western spring wheat to increase the strength.
"Beaver" Flour has the best qualities of both kinds of wheat—the whiteness, lightness, delicate flavour and perfect Pastry making qualities of Ontario winter wheat—coupled with the extra strength of western spring wheat.
Being scientifically blended in exact proportions, the blended wheats are always the same in strength and quality—and so is the flour.
If you have never tried a blended flour, you cannot imagine what a difference there is between "Beaver" Flour and the usual western spring wheat flours. Get a sack of "Beaver" Flour at your dealer's, and try it for yourself.
DEALERS—get our prices on Feed, Coarse Grains and Cereals.
198
THE T. H. TAYLOR CO. LIMITED, - - CHATHAM, Ont.

COFFEE TAPIOCA

1 cupful strong coffee.
2 cupfuls hat water.
6 tablesponnfuls condensed milk.
Few grains salt.
½ teaspoonful vanilla.
¾ cupful quick cooking tapioca.
½ cupful broken nut-meats (optional.)

Combine the condensed milk with the hot water and coffee, add the salt, and when boiling stir in the tapioca. Let cook over hot water until the latter is clear, then stir in the nut-meats and vanilla, and pour into individual molds which have been dipped in cold water. Unmold and serve with top mlik.

BREAD-CRUMB MOLASSES CAKE

3 tablespoonfuls butter substitute.
¾ cupful boiling water.
1 cupful molasses.
¾ teaspoonful salt.
1 teaspoonful soda.
2 teaspoonfuls powdered ginger.
¾ cupful fine dry bread crumbs.
1 cupful Rye flour.
½ cupful ground raisins (optional.)

Combine in the order given, beat well and bake as a single cake or individual cakes, in a slow oven, from thirty-five to forty minutes.

INDIAN DATE PUDDING

Bring one pint of milk to the boiling point. Add one-fourth cupful of corn meal and cook until thick. Add one teaspoonful of butter, one-fourth cupful of sugar, one-half cupful of dates cut in small pieces, two well-beaten egggs, and one-fourth teaspoonful each of cinnamon and salt.

Mix well and bake in a buttered pudding dish in a hot oven until firm. Serve hot with lemon sauce.

RHEUMATISM AMONG YOUNG CHIDREN

Rheumatism is becoming quite prevalent amang children, and it is a subject of vital interest to mothers. Its importance cannot be over-estimated, because, in the first place, rheumatism in children so often goes unrecognized its existence not often being thought of until it has produced untold injury to the heart.

Again, neglected and improperly treated rheumatism in a child in most cases results in a state of chronic invalidism for the remainder of life. In rheumatism affecting children, there is one organ which receives the brunt of the attack. It is the heart, and it may be left with a scar which never heals, so weakening it that it easily breaks down under the least added strain.

If there is one disease in childhood a mother should use every safeguard to protect her child against, it is rheumatism. One might easily point out as peculiarities of rheumatic fever in There will be a comparatively mild inflamation of the joints. There is in practically every instance involvement of the heart. And what is perhaps of the greaest interest is the fact that ofttimes i nchildren the heart involvement will be the only symptom of the attack. Rheumatism in children often starts with the heart being involvtd as the first and only symptom. Rheumatism in children always has a tendency to recur, and each succeeding attack only adds a greater injury to the heart.

"What does one raise when he sows wild oats?" asks a correspondent. Well, we know one young man who raised cheques. And his crop led to a close crop in the State's prison.

If You Ever Want Credit

at a bank or elsewhere, the fact that you have built up a substantial Savings Account will help you get it.

FEED SITUATION THIS WINTER MOST ACUTE

(Continued from page 580)

(j) Provide funds wherewith to purchase, manufacture, mix, store, ship, carry and deliver the said ingredients and feeds.

(k) Sell the said feeds at a price not to exceed $—— per ton over the actual cost of the ingredients, delivered at the mill, warehouse or other storehouse of the Millers.

(l) Furnish the Committee when demanded with samples of the said feeds for the purpose of analysis and so manufacture the said feeds so that at all times shall they be upon analysis at Ottawa equal in food values to the standard set by the Committee in accordance with the said formulae.

2.—The Committee shall

(a) FuFrnish to the Millers approved formulae for the mixing and manufacture of the said foods.

(b) Approve of the sources of supply of the said articles and ingredients.

(c) Arrange with such persons or corporate bodies as shall have the matter in charge in Canada and the United States that the said articles and ingredients may be exported from the United Staets and imported into Canada.

(d) Receive, recommend and guarantee to consumers or intending consumers the quality of the said foods and the food values thereof as having been manufactured according to the formulae approved by the Ontario Department of Agriculture, as having been subject to sample and analysis from time to time.

(e) Circularise farmers and organizations, advertise to some extent in public and agricultural press and place the machinery of the markets branch of the Ontario Department of Agriculture at the disposal of the Millers ofr the purpose of stimulating the sale and use of the said feeds.

(f) Recommend and assist in every possible way the Millers in the sale of the said foods.

IN WITNESS WHEREOF the parties hereto set their hands, etc.

The circular and agreement published above disclose conditions which are not aat all reassuring. What we can do in the Maritime Provinces to meet the situation is a qusetion which should be occupying the attention of the departments of agriculture of all three provinces. It is a difficult matter to get the ear of a man as busy as the ear of the average farmer is just now. He has his own troubles in the great shortage of labor that confronts him. To just allow matters to drift until the cows need feed, is to invite disaster. Every wide awake agricultural society should take action to bring to the attention of farmers, the pressing need preparing for a change in diet for the stock. This will necessitate new methods of feeding. All this will tend to dislocate things for a time but pretty nearly everything is badly dislocated these days. In regard to mill feeds, it might be well to give this advice that the wise farmer will procure his feed as quickly as he can. He need not be too fussy, either, as to whether he gets bran or middlings. As to being particular this year as to the brand of the feed, it will be so scarce that pretty nearly any quality will look good next winter to the man with stock to feed.

In regard to substitute feeds, the Maritime Farmer has taken steps to ascertain just what kind of feeds will be available, at what price, how long and well they will keep, and in what quantities they can be secured. As soon as the information is available, it will be published for the guidance of stock owners.

One of the feeds which is offering, is re-cleaned elevator screenings at $35.00 per ton f.o.b. Fort William. There will also be balanced feeds, of 20 per cent, protein content available at $61 per ton delivered. The Maritime Farmer may also have a part of 2,000 tons of oil cake to offer at an attractive price. Those interested in these matters should consider carefully their particular needs at once. We shall be glad to give readers any information in our possesion and will be glad to assist in the procuring of feeds at wholesale prices for Maritime Farmer Readers.

Harvest Time is a Busy Time

Every minute counts at Harvest Time. There is no time to take chances with an unreliable Binder—there is too much at stake.

The Massey-Harris Binder

has a long and satisfactory record for Reliability under all conditions. Designed on the best mechanical principles, the best materials obtainable for the purpose used in their construction, and built by skilled workmen who have at their command the most improved machinery and appliances—no expense or pains have been spared to produce a Binder which will do its work perfectly under all conditions, is easy on the horses, convenient to operate, and durable.

GENERAL USE OF VEGETABLES WILL HELP BREAD OUR SOLDIERS

(Continued from page 585)

salt is allowed to each quart jar; one half teaspoonful for the pint jars. After the salt has been added, pour the boiling water over the vegetables up to within one-quarter inch of the top of the jar. **Water should never be added to tomatoes.** If the tomatoes are very juicy, pack them into the jar, add the salt, put on the rubbers and covers, and clamp ready for sterilizing. Or, if desired, a few tomatoes may be cooked to a sauce without the addition of water and used for filling the jars. Corn is a vegetable that requires little water. If the corn is very milky, no liquid need be added to the jar. But if the corn is inclined to be dry, sufficient water may be added to fill it to within one-half inch of the top. For canning fruits, hot syrups of varying densities should be poured into the jars after they have been packed with the fruit. Three parts of sugar to two parts of water makes a good foundation recipe. A thin syrup made by boiling these proportions of sugar and water sufficiently to dissolve all the sugar without making the result sticky should be used for the sweet fruits such as cherries, peaches, apples, etc., that are not delicate in texture color. A medium thin syrup, made by boiling these proportions of sugar and water enough to thicken it and to become sticky, is used this year for all fruits, whether sweet, medium sweet, or sour.

The time scheduled for fruits and vegetables is scientifically accurate. Make your work as accurate, and you will never know a failure in your canning results.

After filling the jars, put on the sterilized rubbers and hot covers. If the Lightning type of jar is used, clamp the upper clamp into position. **Do not touch the lower clamp.** With Mason jars, tighten the cover sufficiently to hold it on the jar, but no more. If an Economy jar is used, put on the cover and snap the clamp on firmly. The capping of tin cans is a very simple process when the mechanical sealer is used. These cans should be sealed immediately after the boiling liquid is added. Adjust the top and place the can in the machine. Raise the can into position by turning the raising lever at the bottom of the machine. Turn the crank with the right hand and, at the same time, gently push the seaming roll with the left hand until it will go no further. Continue turning the crank until the seaming operation is complete, and the crank turns easily. Then the lever having the seaming rolls is pulled toward the operator, and the crank turned as before, until the operation is completed. It only takes a very few turns to complete this process. The jars and tin cans are now ready for sterilizing. This processs may be done either in the hot-water bath outfit or in the steam-pressure cooker. For the woman who has her own boiler, all that is needed is a firm rack to set in the bottom of it to prevent the jars from touching either the bottom or sides of the boiler. These racks may be purchased at a reasonble cost. Fill the boiler with warm water and place the jars carefully on the rack, being sure that they do not touch each other. The water should cover the tops of the jars **one inch at least.** The time of cooking is counted from the minute the water begins to **boil and continues to boil. Count no time that is not real boiling.** Be sure tokeep the tops of the jars covered to a depth of one inch with the boiling water, and keep the water boiling during the whole process.

As soon as the sterilizing is completed, while the products are still hot, remove them from the boiler and place them on a padded cloth or other soft material. Seal the jars tightly Lower the lower clamp of the Lightning jars, and tighten the covers of the Mason jars. Remove the clamp from the Economy jars only after they are thoroughly cold. Invert the jars in a place where there will be no draft but where the products will cool immediately. Allow them to stand for twenty-four hours to test for leaks.

The jars are now ready to be wiped and labeled. Such vegetables as beets and carrots, which are apt to lose their color, should be wrapped in paper and stored where no light will reach them. If the products are not stored in a cool, dry place, they can not be guraanteed to keep.

THE RIGHT WAY TO MAKE THE SIRUP

While fruits may be canned without sugar and sweetened at the time they are used, if sugar is plentiful a sirup may be made and used in place of the boiling water; the fruit is then ready to use when taken out of the jar. The rule for making the sirup is three quarts of water to two quarts of sugar, boiled to a thin, medium, thin, medium-thick or thick sirup.

Thin sirup is sugar and water boiled sufficiently to dissolve the sugar, but is not sticky.

Thin sirups are used for all sweet fruits, such as cherries, peaches, apples, etc., that are not too delicate in texture and color.

Medium-thin sirup is that which has begun to thicken and becomes sticky when cooled on the finger tip or spoon.

Medium-thin sirups are used in the canning of the medium-sweet fruits, such as blackberries, currants, dewberries, huckleberries, raspberries, etc.

Medium-thick sirup is that which has thickened enough to roll or pile up over the edge of the spoon when it is poured out.

Medium-thick sirups are used in the canning of all sour fruits, such as gooseberries, apricots, sour apples, etc., and delicately colored fruits, such as strawberries and red raspberries.

Thick sirup is that which has become so thick that it is difficult to pour out of a spoon or container, but is not sugared.

Thick sirup is used in preserving and making all kinds of sun-cooked preserves.

TEN ADVICES IN JELLY MAKING

1—Seect firm underripe fruit which is fairly acid, containing a large amount of pectin.

2—When cooking the **fruit** to extract the juice, allow it only to simmer and do not stir.

SHERWIN-WILLIAMS PAINTS & VARNISHES

Your Home Needs Protection

You can't afford to "let the painting go this year". Rot and decay are the greatest menace to property. You keep up life and fire insurance—why neglect your home?

A little paint or varnish on the outside or inside *now* will save you much greater expense later on.

LOOK IT OVER! THINK IT OVER. PAINT IT OVER!

RELIEF AT LAST

I want to help you if you are suffering from bleeding, itching, blind or protruding Piles. I can tell you how, in your own home and without anyone's assistance, you can apply the best of all treatments.

PILES TREATED AT HOME

I promise to send you a FREE trial of the new absorption treatment, and references from your own locality if you will but write and ask. I assure you of immediate relief. Send no money, but tell others of this offer.
Address

MRS. M. SUMMERS, Box 309
Windsor, Ont.

3—Never cook fruit in a tin or iron vessel.

4—Never cook fruit with lid on the vessel.

5—Boil the strained juice rapidly but not hard, and do not overcook.

6—Make jelly in small quantity quickly.

7—Have the jelly glasses ready in a pan of hot water when the jelly is cooked.

8—If jelly is not firm, set it in the sun and cover it with a pane of glass or put it in a slow oven for a few hours.

9—Store in a cool, dark, dry and well-ventilated room.

10—Avoid "overdilution of juice, oversupply of sugar, overcooking of juice and sugar."

REASONS WHY JELLY "FAILS"

If it is tough it has too little sugar.

If it crystallizes it was stored in a warm place, has too much sugar, the sugar was added at the beginning or at the ending of the cooking, or it boiled too rapidly.

If it is fermented it was stored in a warm, damp place, or was not boiled sufficiently.

If it is moldy it was not properly covered, or was stored in a damp, poorly ventilated place.

If it is gummy the juice and sugar were cooked too long together.

If it is soft it contains too much sugar.

If it is too dark it was cooked in tin or iron vessels, the juice was overcooked or the juice and sugar were overcooked.

If it is cloudy the fruit was not clean, the fruit was not allowed to simmer when preparing the juice, the fruit was stirred when preparing the juice, the juice was not strained adequately, the jelly bag was pressed, the strained juice was allowed to simmer instead of boiling rapidly, or the sugar was added in the beginning.

TWICE TEN ADVICES ON CANNING

1—Follow one set of instructions only.

2—Begin your canning work the first day with a small quantity and with one product. Work carefully. Test before you can a quantity.

3—Prepare at any one time as many cans only as can be processed immediately.

4—Work quickly.

5—Have plenty of boiling water on hand.

6—Use soft water free from excessive quantity of mineral matter.

7—Use only the best types of jars.

8—Tighten the wire bails of glass jars each year before the canning season begins.

9—Never use a rubber more than once.

10—Scald or blanch in boiling water. "Do not count time until water jumps."

11—"Cold dip" in very cold water.

12—Pack jars with vegetables or fruits to within ¼ or ½ inch of top.

13—Do not add too much salt to vegetables.

14—Cover fruits or vegetables in jar with boiling liquid.

15—Place peas, corn, beans or asparaus in the canner as soon as packed.

16—Have the water in the canner boiling vigorously all over the surface.

17—Place the jars in the canner on racks with the water at least 1 inch over the top.

18—Count the time of sterilizing when the water begins to jump.

19—Cool the jars quickly.

20—Do not store until cold.

DRAINAGE A WAR AND PEACE MEASURE

Since it is necessary for us to supply our allies with food. it behooves us ot put every acre into cultivation that we possibly can.

There are at the present time thousands of acres lying idle on account of seeped condition of the land. This land can be rendered productive by the instalation of drainage systems thereon. Thousands of acres were reclaimed last year in this way that will be in csultivation this year, and the coming summer should see a much greater area reclaimed. Consequently we may look upon the drainage of land as a war measure in that it augments production. There is one important feature which distingushes the drainage systems as war measures.

Every dollar which today is put into a project of this kind is with the idea of increasing the productivity of the soil, and this will return interest in peace times as well as in war times. It would be most excelent if the same could be said of other necessary war activities in which the country is engaged at this time. Uunfortunately that is not the case. The weapons of offense and defence which are forged at great cost cannot be put to any peace-time use.

CONTROL SWARMING AND CONSERVE THE LABOR OF BEES

One of the greatest problems in beekeeping today is the control of swarming. It is natural for a strong colony of bees to swarm in early summer when honey is coming in. but the breaking up of the colony cuts down the honey yield; while watching for and hiving swarms takes a great deal of the bee-keeper's time, and the swarm may escape notice and fly away.

The methods of controlling swarming that have been tested at the Central Eperimental Farm. Ottawa, fall under three heads.

(1)—General measures. Partly shading the apiary; providing a large entrance with deep space between combs and floor; giving plenty of room in the brood chamber and sueprs; and young queens. These measures, while valuable have been insufficient in themselves to prevent the bees from raising queens in preparation for swarming.

(2)—Manipulations to prevent more than one swarm. The queen's wings are clipped, preferably during fruit-bloom, and when a prime swarm issues and is still in the air, the queen is picked up from the ground and placed in a cage. and the hive is removed to a new stand. A new hive containing the caged queen is then placed on the old stand to receive the returning swarm, the queen being liberated later. The field bees join the swarm leaving the parent hive so much weakened that it is ont likely to swarm again. To make certain of this, however, the parent hive may be merely truned around and not removed to the distant stanad until five days later. This method of swarm contdol necessitates immediate attention when the swarm issues. but. as the manipulations are simple, they can often be carried out by the home folks should the bee-keeper be away.

(3) — Manipulations to prevent swarming altogether. At the time of writing, none of the manipulations that have been tried have succeeded except the cutting out of all queen-cells every seven or eight days, and this failed during a heavy honey flow from clover at Ottawa in 1916 when the bees raised queens from worker larvae. and swarms issued before the queen cells were capped over. It has, however, been found possible to prevent swarmingin out-apiaries, forty miles north of Ottawa. by this means, although it entailed weekly visits from the middle of May until the middle of August. and much time spent in examining each colony.

Experiments in the control of swarming are being continued, especially along the following lines. which seem the most promising.

(1) Testing systems of raising brood to the super. Many of these will delay swarming under come conditions.

(2) Finding means by which the brood chamber may be easily examined without lifting off the supers. A hive in which the brood combs are in a rack that can be drawn out sideways is being tried.

(3) Endeavoring to breed a strain that will not swarm, of which the preliminary step is found out if the non-swarming character shown by some queens is inherited. A queen showing this character was found to retain it the following year.

The Paint for the Barn

The barn is usually the most valuable building on the farm; it houses several thousand dollars' worth of stock, implements and foodstuffs. Don't leave so much valuable property unprotected. Safeguard it with

"HOMESTEAD LIQUID RED"

This is the best wearing and most economical paint for all farm buildings. One gallon covers 300 square feet, two coats, where the wood is in good condition. It's a wise investment to let this good paint protect all your farm buildings.

Paint the house with CANADA PAINT; decorate the walls with C.P. "SANITONE"; freshen up the furniture and floors with C.P. "SUN VARNISH STAINS". Ask the C.P. agent in town for further particulars.

Our book: "What, When and How to Paint" mailed free upon request.

DECORATIVE SERVICE FREE. Our suggestions and color schemes for finishing any part of the exterior or interior of your building would be helpful to you.

THE CANADA PAINT CO. LIMITED,

Makers of the famous "ELEPHANT BRAND" White Lead.

572 William Street, Montreal. 112 Sutherland Ave., Winnipeg.

3

SILO AS INDIEPENSABLE AS ANY OTHER PART OF FARM EQUIPMENT

In these times of high-priced feeds the silo is as indispensable to the farmer as any other piece of farm equipment. Many farmers would be better off if they had less other farm equipment and a silo or two. Silos mean livestock, and livestock means more pasture. hay, corn. other grains, and farm manure.

Live stock means enriched soil, larger crops, more money for the farmer, and plenty of prosperity for everybody.

Livestock means more meat, milk butter, cheese, and slothing for our soldiers. No nation can exist without an ampde supply of animals.

More livestock brings up the question of prodpcing and conserving feed. The passing of the range and the decrease in the fertility of our land have put us face to face with a serious problem. Production can be increased by the growing up of legume plants and bw feeding crops to animals and applying the manure to the soil. As fertility is increased, more food stuffs will be produced.

Silage should be considered by the farmer in the same light that the house-wife considers her canned fruit. a provision for future needs. The advantages of the silo are many. and if these were known to the farmer, more silos would be built. More of the corn crop can be saved by the use of the silo than is saved in the ordniary way. With the best methods. ordinarily about 33 per cent. of the crop is lost, and under certain conditions, it may far exceed this amount, but with the silo there is no loss except what is caused by fermentation. This is very small. Any method that will enable the farmer to get more out of his crops will increase the returns from his land. With the silo, our land will return one-third more than without it.—R. W. Clark.

CLEANING AND STORING SPRAYER

After the spraying season is over, generally the spraying machine is run into a shed and left until next spraying time again. But the condition of the machine when you next attempt to use it is going to be all wrong unless it was properly cleaned out after last using. More than one fruit grower and marketman has lost money because he waited until he wanted to spray to see if his machine was in working order. While he lost time working on the machine, opening up clogged nozzles, etc., the bugs were getting started on the crop.

Spray materials act on the interior of the spraying machine, corroding it more or less, especially in the case of lime-sulphur mixtures in iron pumps. Paris green is especially bad, since it does not readily dissolve in the spray mixture and tends to settle out of solution, clogging the pump or nozzles. One case of an unworkable field sprayer which came to my attention this season was caused by the compression chamber being completely filled with Paris green accumulations of the previous season.

When the last spraying is given, a couple of tankfuls of water should be run through the pumps at high pressure before putting it away. This will take the spray material out of the pump, and prevent the formation of scale on the inside of the pipes which would give much trouble clogging nozzles next season. The nozzles should be removed and stored away where they will not be lost. J. T. R.

SHEEP TREATED FOR INTESTINAL ROUND WORM

Sheep suffer from parasites to a greater extent than all other ailments combined. One of these is the intestinal round worm; the common name for it is "knotty gut." The life history of the worm has not been fully worked out, but it is known to be communicated from one sheep to another. It is possible by persistent use of worm medicine to dislodge the mature worm, but nothing can be done to remove the warts or nodules.

Medicines that have proved of value as preventatives are tobacco, copperas and turpentine. They can be fed in connection with salt. Use one pound of salt to four pounds of tobacco leaves. Another method is to use equal weights of salt and copperas, or salt saturated with turpentine. These may be kept before the sheep at all times. There is something wrong with the feeding arrangement of sheep when they are seen to eat snow.

It is one of the greatest fault of those who keep a few ewes or a large flock, that good, clean drinking water is not before tehm at all times, and salt, mixed with medicines, to allay the ravages of parasitic diseases, the worst diseases that the Canadian sheep breeder has to contend with.

GIVE GROWING PIGS MINERAL MATTER

The United States Deparment of Agriculture suggests the following mixture be placed at the disposal of growing pigs. It wil not only supply some light mineral constituent, but is said to be valuable in preventing worms:

Charcoal	1 bushel
Hardwood ashes	1 bushel
Salt	8 pounds
Air-soaked lime	4 pounds
Sulphur	4 pounds
Pulverized Copperas	2 pounds

Mix the lime, salt and sulphur thoroughly and then mix with the charcoal and sahes. Dissolve the copperas in one quart of hot water and sprinkle the solution over the whole mass, mixing it thoroughly. Keep some of this mixture in a box before the hogs at all times, or place in a self-feeder.

SILAGE VALUABLE SHEEP SEED

The most successful sheep men of the country are awakening fast to the great value of silage as a sheep feed. Silos are fast making their way into the western range country and the sheep are receiving their share of the result.

What would be termed good quality silage for dairy cows will also prove wholly desirable for sheep. Most sheep meen feed from two to four pounds daily a head to sheep, and from one to two pounds to lambs. When lambs are on full feed of grain such as corn, and are also receiving fair allowance of hay, they will, as a 1½ pounds daily. Breeding ewes should not be overfed before lambing season. Make 2½ pounds the maximum feed a day. After lambing this may be slightly increased.

Silage acts as a desirable appetizer, and serves to keep the digestive organs in healthy condition. It should not comprise more than half of the ration.

GIVE CALF A GOOD START DURING SUMMER

The calf shows very quickly the effects of poor care, and this often occurs during the summer months because of the pressure of other work, although it is really much easier to keep a calf thrifty in summer than in winter. Calves grown on farms should have grass pasture provided for them and should be fed some rain, preferably oats, during the first five months of their life. In taking them from the cow and raising them by hand on skim milk, you are preventing them obtaining butter fat, which is a natural part of the food of a young animal. You must replace this, insofar as it can be replaced, by the use of a grain rich in oil, fed to the young animal on grass, the grass itself, taking the place of the butterfat in milk to a small extent. A calf grown upon swim milk, grass, and a small amount of oats, will be a profitable, healthy, strong, and rapidly growing animal, while a stunted calf will require much more feed next winter to get him started towards making good gains.—G. E. Morton.

STICKING BUSHINGS

Binding of the bushings that surround the push rods frequently causes trouble. This may be caused by the oil becoming gummy or by valve grinding grit that has gotten down into the interior. If the aperture is closer with a cloth before the valves are ground this latter trouble will be obviated.

The style here illustrated is Queen Anne —a veritable "object d'art."

The Supreme Achievement in Sound-reproducing Instruments

Pathephone

THE most remarkable musical instrument in the world—the culmination of a quarter of a century's scientific progress. The Pathephone is something different—something better than you have ever known.

The Pathephone excels others because it not only embraces ***all*** of the most desirable features possessed by other instruments and has them in their most perfect development, but it also has many points of superiority exclusive to itself. Furthermore, the combination of the Pathephone and Pathe' Records presents to music lovers an offering that is unrivalled, for the Pathe' method of recording, with its long, broad sound-wave and the reproduction by means of a smooth Sapphire Ball instead of a digging, scratching needle, produce a tone wonderfully full—rich—natural and indescribably sweet.

Consider these big Pathe' advantages—

The Permanent Sapphire Ball—no digging, tearing needles to change.

Records that will wear thousands of times.

An all wood tone chamber (on the principle of a violin.).

Pathe' Tone Control—regulates the volume of sound.

Plays perfectly all makes of records, as well as the Pathe'.

The exclusive period design cabinets. Exquisite furniture for every home.

A complete line of instruments to meet every purse.

A repertoire of double disc records, unique, comprehensive and artistically perfect.

PATHE PERIOD DESIGNS

It is fitting that the Pathephone, which has attained such signal superiority in musical and mechanical directions, should also lead the way in the beauty of its appearance.

Exquisite examples of furniture periods most famous in history have been selected as the models for the Pathe' Period Cabinets. The result is a collection of instruments unique and beautiful that will harmonize perfectly with the most exclusively furnished home.

Everyone interested should write for the PATHE ART CATALOGUE, containing interesting chats on period furniture.

THE PATHE' FRERES PHONOGRAPH COMPANY OF CANADA, LIMITED

4-6-8 Clifford Street - TORONTO, Ontario 3

Territory open for live Agents. Progressive Merchants writing on their business letter head will receive a confidential booklet on the possibilities of a Pathe' Agency.

METHODS OF WEANING LITTLE PIGS

Weaning time is the most critical period of the hog's life. The approved practice is to wean at about six weeks. Teach the litter to eat three weeks before weaning, using a crib or creep which excludes the sow, or a separate pen. Feed, in a trough, preferably, middlings with skim-milk. With middlings at present unobtainable, finely ground sifted oats is best. Feed only small quantities at first and avoid having decomposed or stale food left over. After weaning, add shorts gradually up to equal parts and from the secon dto third month add barley or corn as one-third the total meal ration. First and last, avoid over-feeding with its consequent train of evils.

Within the last year at the Central Experimental Farm, experiment and subsequent practice has indicated a system whereby weaning is simplified and th ebad results of careless feeding practically eliminated. Instead of "hand-weaning" or feeding the weaning pigs milk and meal in a trough, a small self-feeder is substituted in the creep, skim-milk being fed in a separate trough. Finely ground oats and shorts, and later ground elevator screenings with a small proportion of ground corn, if available, are placed in the feeder. Thus, the little pig feeds himself when and as much as he sees fit, is able to eliminate from the meat eaten much fibrous material which he must consume willy-nilly where fed a slop, an dincidentally accustoms himself gradually to skim-milk. Except in cases of early litters, the little pigs are given access to outdoor runs at all times from two to three weeks of age. Excellent growth is shown, the pigs developing clean, long and thrifty, with no evidence of thickness, pudginess or lack of energy. Absolutely no evidence of indigestion or scouring has been seen, and in one instance where a dozen litters were so fed at a central feeder the percentage of "culls" was remarkably low. When finally removed from the sow, pigs so weaned, particularly where they are self-fed subsequently give minimum evidence of the check in growth, usually incidental to weaning in a greater or lesser degree. In short, while the experienced hog-man can hand-wean his pigs with maximum results, the farmer lacking experience or depending upon ever changing attendants, is likely to run into difficulties. The method described besides reducing labor apparently removes the danger of irregular and over-feeding. Both method and results might be described as automatic.

In the foregoing method, skim-milk plays an important part. Where this or other milk product is unobtainable, experimental evidence would show that good pigs may be raised by following this method and supplying tankage, blood-meal, fish meal or some similar animal product in a separate compartment of the feeder, not mixed with the regular meal. Pigs, so fed, have shown only slightly inferior in quality to skim-milk fed olts, but the cost to produce would seem to be considerably increased.

AS OTHERS SEE IT

The endorsement of men who breed and raise cows to record breaking form are safe ones to be guided by.

Championship cows are not experimented with. The best methods only are used in caring for them. Experience, not argument, proved to such well-known breeders as Mr. G. A. Brethin of Norwood, Ont.—that Empire Milking Machines provided the best means of milking even champion, record holding cows.

Mr. Brethin in a letter of March 18th last writes that the official records of Hillcrest Pontiac Susie, Hillcrest K.P. Ranwerd, Hillcrest May Pontiac and Hillcrest Sadie Ormsby were made with the Empire.

He says further,

"We have a 20.81 lb. two year milking up to 77 lbs. in. one day (first calf,) a 29.31 lb. three-year-old milking over 80 lbs. with second calf and increasing, and a 34 lb. six-year-old milking up to 122.5 lbs. in one day and 3216 in 30 days. All milked in test with Empire."

Remember, an Empire Milker will do the work of three men and in the same time. It saves time, labor, the cost in wages and board of hired men and eliminates the drudgery of milking.

Empire Milking Machines are used on Governmental Experimental Farms and Stations and by Agricultural Schools and Colleges throughout Canada.

MILK IN THE HOG RATION

In order to raise and finish all the extra pigs that will be farrowed in Canada this year as a result of the campaign for increased production, it will be necessary to exercise the utmost economy in the use of concentrated foods. Pig raisers who have access to dairy by-products have a great advantage over others. Experiments have proven that when meal is worth $40 a ton, milk is worth more than $8 for an equal weight, that is, provided it is fed economically. Experiments carried on at the Dominion Experimental Farms and Stations show that for growing hogs, 60 lbs. and over, 400 lbs of skim milk produced results equal to 100 lbs. mixed meal. Buttermilk fed fresh is equal to skim milk. Whey is not so valuable. One hundred pounds of whey was proved equal to 19.2 lbs. of milk, that is, provided it is fed in not too large quantities and before it has soured.

A stud yof experiments with skim milk show that for young pigs 1 lb. of milk fed with 2½ or 3 lbs. of meal gives bes tresults. For larger hogs les milk may be used. For hogs over 100 lbs. in weight not more than 5 lbs. of skim milk daily should be fed in order to get the greatest value from the milk.

At the Nova Scotia Agricultural College it was shown that the best gains were made by feeding a lot of pig ration composed of 148 lbs. of grain, 900 lbs. of skim milk, and 110 lbs. of mangels. At the Ontario Agricultural College the best results were obtained where the proportion of milk to meal was 2.5 to 1. In one trial in which this proportion was used, 365 lbs. of skim milk were equal to 100 lbs. of meal. This agrees fairly closely with the results obtained at the Ottawa and Branch Farms.

In a series of articles that appear in the May number of the Agricultural Gazette, both Ottawa and Guelph authorities agree that it does not do to change the diet from sweet to sour milk. For young pigs the sweet milk is much to be preferred. For larger pigs it seems to make little difference whether or not it is fed sweet or moderately sour, provided whatever condition favored is uniformly kept up, that is to say, if the milk cannot be obtained always sweet, then it should be fed sour as a rule.

SWAT THE FLY BEFORE ITS BIRTH

The most important way to control the fly nuisance is to swat the fly before it is born. Clean the stables and yards and keep the garbage cans covered. The following are very convenient and effective fly poisons:

Bichromate of potash, one dram in two ounces of water. Add a little sugar This mixture is not dangerous to human life.

One teaspoonful of formalin in one-fourth pint tof water . This must be kept away from children and house pets.

To quickly clear a room where there are many flies, burn pyrethrum powder and sweep up the flies.

Household Furniture

AUCTION SALE JULY 17th, 1918, at 1 P. M. Sharp

I am selling at public auction on this date, my entire herd of 25 Pure Bred Ayrshires, also all other stock and implements and Household Furniture, as I have sold my farm and am going West. This will be a sale of exceptionally high class stock and is positive. Breeders wanting extra fine sires from R. O. P. dams with large records, also choice young females, cannot afford to miss this sale. This will be the largest sale of R. O. P. Ayrshire Stock ever held in the Maritime Provinces.

The first herd sire was Prince George of Willow Farm, No. 35736, whose sire was Stadacona Conqueror No. 28836 and dam Gurta II. of Allendale 25405. Her R. O. P. records for 3 successive years was 34210 lbs. milk and 1232 lbs. fat and winner of Halifax Herald Silver Cup given in 1916 for best pure bred cow, any herd, on Exhibition Grounds.

The second herd sire was Flavius of Ottawa No. 43178. Sire, Monarch of Tanglewyld No. 34626 and dam Flavia 3rd of Ottawa No. 28100, with R. O. P. record of 8609 lbs. milk and 342 lbs. fat. We have several fine heifers after this sire and now bred to our present herd sire (3rd).

Present herd sire is Prince of Rosemont 3rd No. 48032. He is 3 yrs. old. Sire Rospitt No. 34386 (whose dam was milkmaid 4th 12374, the dam of Milkmaid 7th). His dam is Rose No. 31884 with R. O. P. record as 2 yr. old of 10795 lbs. milk and 435 lbs. fat, and as 4 yr. old with 12913 lbs. milk and 485 lbs. fat in R. O. P., and has since qualified in R. O. P. as mature cow with large record. He is always first prize winner. He is in this sale.

Also one bull 10 months old, whose sire is our herd sire and dam is Princess Pat of Willow Farm No. 39501. This is fine calf and fit to head any herd.

BELOW IS LIST OF SOME OF THE COWS OFFERED:—

There will be three daughters of Gurta II. of Allendale 25405, two of them whose sire is Hillside Napoleon (Imp) No. 32200. These two cows and their dam and another cow in this sale, headed by our herd sire, won Silver Cup given by Halifax Chronicle in 1916 for best dairy herd any breed on the Exhibition Grounds. One of these cows, whose picture is on this page, Princess Pat of Willow Farm No. 39501, has R. O. P. record as 2 yr. old of 9376 lbs. milk and 383 lbs. fat. We have a fine heifer from this cow due to freshen in August.

East Court Sea Foam No. 37544—sire, Wee McGregor 28682, dam Gardrum Ocean Girl, No. 28219. She produced in R. O. P. as 2 yr. old 8849 lbs. milk and 407 lbs. fat and qualified as 4 yr. old in R. O. P. with 11084 lbs. milk and 493 lbs. fat in 342 days. During this test 5 weeks after freshening she produced 69 lbs. milk per day, testing 4.1%. Three fine heifers from this cow will be in sale.

Lady Lilly No. 37147, qualified with 10150 lbs. milk and 424 lbs. fat in 329 days and freshened again inside of 12 mos. Two of her heifers will be in this sale.

Lady Gertrude of Spruce Row, 44582, sire, Howies Crusader (Imp), 26363 in R. O. P. registered, and dam Lady Kirsty of Glenora 1957, (with R. O. P.) Lady Gertrude qualified as 2 yr. old with 5767 lbs. milk and 271 lbs. fat. She will have a heifer 1 yr. old in sale.

Also several other high class young cows, some fresh, others due this fall or early winter. Also Grade Ayr. and Guernsey cows and heifers. The oldest cow in sale is 7 yrs. old.

Also one Pure Bred registered Clydesdale filly, 3 yrs. old, weight about 1400 lbs. This is an extra fine clean limbed mare. Color, dark mottled brown. Also one filly, 1 yr. old, sired by Alto Axworthy and one Clydesdale colt, 10 mos. old.

Also 8 young grade Shropshire ewes and lambs.

Also 1 brood sow and six spring pigs.

Also, wagons, sleighs, harness, chains, forks, scales, power hay cutter and farm tools. Also household furniture.

Also 100 bu. oats, 25 bu. wheat and 2 ton pressed straw.

TERMS OF SALE:—3 months credit with approved joint notes. All amounts under $10 to be cash, and 2% discount for cash on amounts over $10.

C. C. FULTON,
Auctioneer.

ARTHUR S. DENNIS,
Stewiacke, Colchester Co., N. S.

DON'T FORGET THE DATE, JULY 17th, 1918. ONE MILE FROM DEPOT.

HOME GROWN CLOVER SEED IS THE BEST

It has repeatedly been demonstrated that there is rather grave danger in using imported red clover seed, for the reason that imported seeed often does not produce the crops that it is expected to produce. Imported seed may germinate beautifully, a magnificent stand may be secured but, alas, in the spring following the seeding there is often disappointment in store for the farmer who has sown imported seed. He often finds the clover more or less killed-out.

This killing is often due to alternate freezing and thawing in the spring, causing heaving of the soil and killing of the clover, but in many cases the killing is due to the fact that **imported clover seed produces a crop that is too tender for the Canadian winter.**

Clover raised from imported seed does not stand the winter nearly as well as clover grown from seed raised in Canada. In other words, whenevei Canadian-grown seed is used, the crop is likely to come through the winter in much better condition than when imported seed of a less cold-resistant type is sown. The stand of clover raised from Canadian-grown seed is consequently apt to be thicker and more vigorous and, as a result, heavier hay and pasture crops can be expected than when imported seed is used.

That heavier crops are realized from Canadian-grown seed has been amply demonstrated by the Experimental Farms' system and under the circumstances it is our opinion that **Canadian-grown should, whenever possible, be used in preference to imported seed.**

During the last few years especially, a great number of farmers have followed the suggestion to use "home-grown" red clover seed and, as far as can be ascertained, no one has complained of the results. On the contrary, any one who has used seed on his own farm or in his home district, has been well satisfied with the crops realized.

In view of this we would advise every farmer who has a red clover field to set aside part of it for the purpose of producing a crop of seed sufficient to supply at least his own demands. The importance of using home grown seed may be overlooked by many who for years have been accustomed to secure their supply from the nearest store, but it is our opinion that **the farmer who raises his own clover seed is well advised.**

MARITIME WOVEN WIRE FENCING

The Fencing That Does Not Bend or Break

ALL fences manufactured by the New Brunswick Wire Fence Co. Ltd. are made by the most skilled labor and of the very finest materials.

The new slide locks are outstanding features in this fence. Every other device used in this fence to prevent side slipping or up and down movement has been thoroughly tested and is guaranteed to give satisfaction.

Every yard of fencing shipped by us is thoroughly tested before leaving the factory. Our fences are not painted, but are galvanized.

We also can supply you with steel frame gates, panel fencing, etc.

Our fencing is sold by dealers in nearly every section of the Maritime Provinces. If there is no dealer in your locality write direct to

New Brunswick Coming to the Front in Sheep Raising

Dog Tax Reduces Number of Curs

For many years the Editor of the Maritime Farmer advocatetd a tax on dogs for the better protection of the sheep industry of the aMritime Provinces. A little over a year ago the New Brunswick Legislature enacted a law whereby, on the petition of twenty-five or more property owners in a county the County Council shall tax every dog in the Municipality and thereby create a fund from which losses incurred by sheep owners by the ravages of dogs will be made good.

The majority of the Counties in the Province of New Brunswick have put the act in force and it is working splendidly.

We met a farmer in Gloucester County a few days ago who said his thoughts had referred to the editor of the Maritime Farmer a few days previously when no fewer than twenty-five dogs in his vicinity had been hastened across to the happy hunting grounds the next day after the tax collector had gone his rounds and collected the 1918 dog tax. A lot of useless lamb killing curs have been put out of business in other sections of the Province. May the good work go on. We are satisfied that the agitation carried on by the Maritime Farmer and the New Brunswick Farmers' and Dairymen's Association is bearing the fruit of reddess to an industry that for many years had been going to the dogs.

There never was a time in the sheep industry's history when mutton, lamb, wool and breeding stock brought such remunerative prices as they do at present. It will be many moons before prices will, if ever, droy to the low pre-war level.

The New Brunswick Department of Agriculture, wishing to encourage the sheep industry as much as possible, is making provision whereby farmers who wish to engage in this industry, but who may not be financially able to secure a flock, may procure the financial backing they require.

The Act reads as folows:

BILL

An Act to Provide for the Purchase and Sale of Sheep

BE IT ENACTED BY THE LIEUTENANT-GOVERNOR AND LEGISLATIVE ASSEMBLY AS FOLLOWS:

1. The Lieutenant-Governor-in Council is hereby outhorized, upon the recommedation of the Minister of Agriculture, to purchase for the Province such a number of sheep for breeding purposes as he may determine to be in the publis interest, and for that purpose may incur an expenditure to an amount not exceeding fifty thousand dollars ($50.000) which amount shall be paid out of the revenues of the Province, and said sum shall be returned to the Public Treasury from the proceeds of the sale of such sheep immediately sale is effected and deliv- returnde to the public treasury from the proceeds of the sale of such sheep immediately sale is effected and delivery made.

2. The Lieutenant-Governor-in Council may guarantee payment of any advance made to any farmer by any chartered bank with the Province up to an amount equal to two-thirds of the selling price, if not more than twenty-one sheep.

3. Such sheep shall be resold by the Minister of Agriculture, at such times and under such terms and conditions as to their being kept within the Province, and otherwise, as may be determined by the Lieutenant-Governor-in-Council.

Buyers Agreement

The undersigned agrees to purchase from the Honourable Minister of Agriculture for the Province of New Brunswick, the folliwing sheep, namely:————ewes and———— pure bred ram upon the following terms:—

1. To deposit $3.00 per head of said ewes and $10.00 per head of said ram, upon signing of this agreement, said deposit to be forfeited if sheep not accepted except under extreme and unforseen circumstances.

2. To take delivery of said sheep at any time that the Honourable Minister of Agriculture may be able to deliver same. Said date not to be later than the fifteenth of December, 1918.

3. To supplement the cash deposit mentioned in paragraph (1) herof when the said sheep are delivered so that the deposit shall amount to one-third of the gross purchase price of said sheep. Said gross purchase price shall be the actual purchase price paid by the Government of New Brunswick for said sheep together with all freight and handling charges on same.

4. To give a note for the balance, payable in one year, with interest at six per cent, per annum until paid, whether paid at maturity or not, and any other security required by the Manager of the Bank through which this purchase has been made.

5. Not to sell, kill for market or home consumption or otherwise dispose of said sheep until all claims against said seep are paid, without the written consent of the Manager of the Bank through whom this purchase is made.

6. The liability of the undersigned to pay said note shall not cease by reason of the loss of said sheep through death, by accident or disease, or any other cause, or from straying.

Dated t————N. B., this———— day of————A. D., 1918.

If any of our New Brunswick readers would like to take advantage of the financial assistance thus offered it will be well for them to get in touch with their local banker without delay.

SENTIMENT OR SHEEP

Under the above caption a timely article on the sheep question in a recent issue of the Country Gentleman. We are reprinting the article in question for the benefit of our readers.

Some years ago the late Senator George G. Vest stabbed a great American industry with the sharpest weapon in the world. As a result of his and similar attacks the Government is now embarrassed to clothe its soldiers and it has been forced to add the regulation of another business to its long list of duties.

It is not at all likely that Senator Vest had even a remote inkling of the consequences when he pronounced his eulogy on the dog. He was a very eloquent man who doubtless liked to hear the sound of his own voice. Also he was a lawyer, and it was as a lawyer that he appeared in court and immortalized a dog ,possibly a dog that he never saw, and quite likely a worthless cur. Had chance given him employment where denunciation of a dog was in his client's interest, no doubt he could have done it masterfully.

But Senator Vest's great opportunity for a few eloquent words fell on the side of sentiment. There is no answer to sentiment, except more sentiment. Every lawyer knows that. If a lawyer can touch hearts of a jury the opposition may pound and expousd until red in the face, but reason and logic fall as aimlessly as autumn leaves. One tear of sentiment washes away a mountain of reason.

So the gifted senator drew a picture a true picture, of the dog that follows his master with worshipful eyes even to the grave and sleeps across it when other friends have deserted. And thereby he nearly killed the sheep business of the United States.

In the light of statistics, logic reason and experience, there is little doubt of this. Not only have the dogs of the nation killed thousands of sheep but they have discouraged the raising of milions more. When confronted with the facts the dog owner has always fallen back on the matter of sentiment and trotted out Senator Vest's eulogy.

"Now, however, comes Uncle Sam. He points out that there is not enough wool produced in the United States to equip our fighting men. There are no ships to go to foreign lands to get more. He practically confiscates what wool there is to make it go as far as it will, and appeals to the nation to get busy and produce more. At last sentiment bumps into sentiment. The dog owner must choose between his dog and his duty. In many cases he must choose between a dog and a son who is "over there." It will be interesting to see how the choice will fall.

"But to get to the orderly presentation of facts: We were not so particular about reasoning it out when we had sentiment to argue for us, but now that sentiment comes to checkmate sentiment, we dog owners can consistently demand the facts.

"Action was precipitated by the War Industries Board of the Council of National Defense. It has taken over entire control of the wool supplies of the country at a fixed price and from now on our clothing supply, at least at its source, will be in the hands of a Wool Administrator.

Civilians Left Out in the Cold

"It is not difficult to realize the necessity that forced the Government to take the same measures that it did to control the distribution and price of wheat. Unflinching figures prove that our total domestic wool clip is scarcely sufficient to equip an army of 2.000-000, soldiers with the woolen clothing they need, and the uncertainties of wartime transport make our supply from outside a big question mark instead of accurate figures. This leaves the civil population literally and figuratively out in the cold, unless we are prettty well favored by winds to blow the sailing vessels and by good luck in blowing the boche to the bottom. And the whole world is short, the annual clip having decreased 250,000,000 pounds during the war.

"This country finds itself in a particularly bad predicament. We have been obliged to buy from the British colonies and from South America more than half of the wool needed to keep us warm. Great Britain controls easily sixty per cent. of the fine and cross-bred wools of the world and eighty per cent. of the wools used in the finest clothing.

"In 1811 we had 53.633,000 head of sheep in the United States. Now we have, according to the Government estimate at the beginning of the year, about 49.000,000, though many producers and men in the trade claim this estimate too large by several millions. Along with the other sheep-producing countries we are going downhill when we should be preparing to supply our own mills and people. That is the situation with sentiment left out.

"There are those who look upon men who talk of wool shortage as alarm-

(Continued on page 617)

Butter That Will Sell Itself

How to Make it and Prepare it for Market

By George F. E. Story, in Country Gentleman

Nearly one-half the butter made in the country is produced on farms or in small plants as a side issue. There are three classes of people who can profitably manufacture butter at home—the people living on farms at a distance from a cream shipping station or creamery, the surburban reidents who maintain one or two cows and manufacture butter for their own table and the small milk distributor who manufactures butter primarily as a way of disposing of his surplus cream.

It is not necessary to have an expensive outfit with which to make high grade dairy butter. The most important pieces of apparatus are a good churn, butter worker, cream cans, paddles, strainer, thermometer, printer, wrapping paper and ice box. Of these the one of mist imoprtance is the churn. There are many types of churns on the market. None has proved more satisfactory than the barrel churn, unless it is the combined churn and worker type, which is rapidly replacing all other types. The advantage in combining churn and worker is that the butter is worked without being exposed to the air, thereby keeping it cleaner; and during warm weather it can be held for a longer period and more thoroughly worked than butter exposed to the high temperature of the room. The best material for a churn is wood, as earthenware becomes cracked and is very difficult to clean.

Pails, cream cans and dippers should be of the best quality of tin, and whenever they become worn or rusty it is better to have them retinned or buy new ones, as a metallic taste is very often imparted to the butter when the cream stands in a rusty container. A thermometer of th efloating dairy type is an extremely important factor in making high grade butter. Get a printer and paper of the form and size best adapted to the local trade. It is also desirable to have a refrigerator or tank of ice water in which the cream may be held and the butter hardened.

The Right Temperature

The temperature at which it is best to churn will depend upon the season of the year, the feed which the cows are getting and the time which can be given to churning. In the summer time when the cows are on pasture and buttter tends to be soft, fifty-eight degrees is the common churning temperature. In the winter when the cows are on dry feed, man yof them getting cottonseed meal and the majority of them well along in lactation the churning temperature may be raised to sixty or sixty-wo degrees, and even then there maye be some difficulty in getting the butter to gather. If so, the temperature may be raised to sixty-four degrees. Warm water added to the cream will decrease its viscosity and make the churning easier.

Color is added to the cream after it has been strianed into the churn. The amount which is needed depends upon the breed of cows and the feed they getting. Guernseys give milk so high in natural color that many butter makers do not use color. A teaspoonful of standard color to six pounds of butter is the ordinary amount required, although the local demand will govern the amount of color to be used, With a little practice the butter maker will be able to adjust the amount of color necessary.

There are several pointh to be considered in churning: The temperature must be correct and the churn must not be filled more than one-third full, as a churn over half full wil not give sufficient agitation to the cream to bring the butter together. Again, the speed of the churn must be great enough to cause the cream to fall from one side to the other rather than to slide around. Whenever the churn revolves too rapidly the cream may stick to th esides and not be properly agitated. If the cream has become contaminated with certain organisms, or if it is too cold, the cream is apt to stick to the sides of the churn or will froth up making the churning extremely difficult.

Stop the churn when the butter has gathered into granules the size of wheat grains. If churned longer large lumps or masses are formed, from which it is difficult to express the buttermilk, and butter of poor keeping quality is the result. Butter from very ripe cream—that is, cream testing above thirty-five per cent—often comes in large masses, and churned to a high temperature is very often greasy, while, on th eother hand, butter from cream that has less than twenty per cent. of fat in it often forms in hard balls which are difficult to work together to produce a fine textured butter. It requires good judgment on the part of the butter maker to stop the churn at the proper time to insure the complete removal of butter from the buttermilk, and yet not overchurn.

The next step is to draw off the buttermilk. A haircloth strainer is used to strain the buttermilk when it is removed in order that the pieces of butter shall not be lost. For wash water use amounts of water equivalent to the buttermilk drawn off, anad the temperature souldnot vary more than one or two degrees from that of the buttermilk. If the water is colder than the butter it will cause the graules to harden and prevent the proper blending during the printing and working process. If it is warmer than the butter, it is apt to cauase a greasy, salvy butter, especially if thoroughly worked. Revolve the churn several times at each washing.

If a combined churn and worker is used, salt is now added to the butter and is allowed to stand till thoroughly moistened before the rolls are started. The reason for this is that if dry salt is worked into tthe buttter and there is not sufficient water in the butter to dissolve the salt, it will form brine pockets and produce mottles or streaks in the butter. The amount of salt to be added is determined by the market which you supply. High grades of butter are lightly salted, usually one-half ounce to a pound of butter, but the lower grades of butter are usually salted at the rate of one ounce to the pound. Highly salted butter may be gritty unless it carries its full sixteen per cent. of moisture and has been thoroughly worked. If care is taken to have the butter come at a low temperature it will stand much more working without spoiling the grain, and the danger of mottles will be greatly reduced. The danger of overworking butter is important only when the butter is worked at high temperature.

Work the butter till it will break and leave a sharp grain a quarter of an inch long having much the same appearance as broken steel. In handling the butter do not use the hands, but always lift it from the churn to the printing table with the paddles. In using the paddles to work the butter give a strong downward stroke.

The butter is now ready for packing. The manner in which it is packed for shipment depends upon its destination. When sold locally to the home trade it is often desirable to pack in stone jars, as butter keeps better in these containers than in any other. The objection to this form of package is the appearance of the butter on the table. This, however, is not a factor when the butter is made into balls or pats when served. Most people are willing to pay a cent a pound more for butter which is put up in the form of prints, and consequently the greater part of the butter sold at retail is printed. In the East butter prints, with a monagram on the top of the print, are in common use. The difficulty of handling the prints when warm without disfiguring them is an objection to their use. The brick print is used throughout the Middle West and has superseded all other types.

Warm, Then Cool Molds

Molds, paddles and other wooden utensils should be placed in warm water when the churning is started. This fills the pores with water. Before using, however, they are placed in cold water to cool thoroughly. This prevents the butter from sticking to the wood.

In printing butter, a lump which will fill the print to overflowing is cut out of the mass. This is firmly pressed into the print so that a clen, full impression will result. Scrape off the excess with a drawing motion from the center toward either end in order not to pull the butter up from the corners. . Place the butter on a sheet of parchment paper which has previously been soaked in cold water. Where large amounts of butter are made, the butter is printed, allowed to harden, and wrapped later with dry wrappers, but it will be found more convenient in the home to wrap the butter when printed, an dfor this a wet paper is much better. The prints should not be piled one above the other till they have had time to harden. Special racks are of value in handling the prints and for holding the butter in the refrigerator till it is ready for packing.

Parafined cartons into which a butter print may be slipped are splendid if the butter is to be shipped any distance.

After the butter has been printed, clean the churn, worker and other utensils with hot water to remove any trace of butter. Soap or soap powders are good. After washing and scalding with very hot water, allow the woodenware to stand till the next churning. When needed for use again warm water is put in the churn, which is revolved before it is used. The wood will readily soak up and the cream will not stick to the wood if the churn is rinsed with cold water before using.

New Brunswick Wants Sheep

New Brunswick should have a million sheep upon her hill sides.

There are only one hundred thousand now.

Sixty million sheep have been lost in Europe since the war started.

Wool and mutton have risen to unheard of prices. Upon the enterprising farmer the world will depend to clothe the soldiers and feed the hungry. Patriotism and Profit both point the path of duty in this particular.

New Brnuswick's opportunity is at hand. The Government leads the way and lends its assistance.

With the idea of increasing the flocks of the province, the department of Agriculture has arranged in cooperation with the chartered banks, a system whereby large numbers of sheep can be placed in every part of the Province. Every farmer who can buy good lambs locally should do so, but it is not anticipated that the local supply will meet the demand; consequently importations will be made. The manager of every Bank has information regarding the purchase of same. A line of credit under conditions has been established for those requiring it. This Province now has approxiimately 100,000 sheep—there should be at least 500,000. There should be many more pure bred flocks within the Province to supply the yearly demand for pure bred rams; too much money is sent to other parts annually in payment for same.

The Department of Agriculture was aware that the sheep industry in Europe had been greatly depleted and considering the high price paid for wool with good prospects for at least ten years, decided to stimulate the industry. The Minister of Agriculture asked and was given authority at the last sesison of the Legislature to enter into an arrangement with the chartered Banks to buy and sell sheep and finance the transactions.

This Province can become famous as a producer of high class wool and mutton, but every man must be a partner to the movement and activity will be rewarded by ample returns. The slogan must be "Five Hundred Thousand Sheep for New Brunswick."

With an abundance of food and the opportunity there is no legitimate reason why every farmer should not make the raising of sheep an important factor upon the farm. The investment is small; the returns are quick and the interest obtainable upon the capital involved, if proper care be given, is very large. Wool is worth about 75c. to 80c. per pound and last fall good lambs brought from 12c. to 14c. per pound. At the present time wet ewes or shearlings that are serviceable cannot be purchased, because of their value to their owners, but every year sees large numbers of ewe lambs slaughtered, which under present conditions might well be retained for breeding purposes.

The successful farmer today is one who understands Nature; he not only understands but he is very careful not to oppose natural law and to co-operate at every vantage point to the fullest extent; he has learned that nature cannnot be coerced except in definite and direct lines which do not tend to defeat the objects which natural laws are forever constantly endeavoring to attain. What is true of the individual is true of the larger community, whether it be parish, county or country.

Canada has areas eminently adapted for general agriculture, for fruit and vegetable production, for apple growing, for wheat raising. Again there are others where the raising of livestock must be the foundation of successful

agriculture. New Brunswick undoubtedly come in the latter class; while this is true, it does not necssarily mean that the province should not put forth a great effort to maintain her proud reputation as a producer of high class potatoes, but for the farmers throughout the safer policy is to consider livestock production and the agriculture incident to such as the major operation and the one most likely to lead to the establishment of a satisfied, comfortable and moderately wealthy people.

Previous to the outbreak of hostilities ,the livestock population of the world, and particularly of North America, was becoming inadequate to meet the demands made upon it. United States had almast ceased to be an exporter in many livestock products and had actually commenced importing. Canada was fast following in a similar direction. This condition was very apparent in the movement of mutton carcasses from New Zealand and Australia to the Western coast of North America and some came to Halifax. The sheep population of the two countries had dwindled for various reasons, such as the breaking up of the large western ranches, the dog nuisance and to a genreal lethargy on the part of the people in regard to the value of sheep upon the average farm. Very often diseases which are not difficult to treat were allowed to ravage flocks because of the lack of knowledge of proper precautions; ticks took their toll through failure to dip. The low price of wool anad lambs was a feature also. Flocks became smaller and gradually they were done away with and too often their place was not taken with other stock.

Conditions had changed and were on the upward grade before the war. Wool grading and co-operative selling were direct causes of increased prices; the insistent demand from cities for juicy lamb enhanced values; the depletion of the flocks caused shortages at the larger markets, the rapid urban increase and the rural decrease in population upset the balance between the consumer and the producer and rather suddenly many discovered that the sheep industry was worthy of more careful attention. Lambs of standard quality began to soar in price and too often they were not to be had at all and mutton was served instead. But even this substitute did not meet the requirements.

The great depletion in the European flocks since 1914 has for many years to come unbalanced the supply and demand, not for food purposes only, but for breeding also; the farmer with good stock will find a ready market at remunerative prices. America has been wont to go to Europe for her breding stock, but every indication is that the reverse will be true in the early years of peace or at least the exportation from the old lands will cease. New Brunswick today has an opportunity to fill the gap which has been caused by social and economic reasons and by the years of war. Her situation offers excellent marketing facilities, her very rolling lands give pasture suitable for sheep, her climate is not too severe, and the valleys will supply all the hay, roots and the small amount of concentrates to carry large flocks through the winter season. The farmers of the province have a knowledge of sheep raising sufficient to warrant them in the extension of the industry. The co-operative system of selling the wool guarantees the best price the American or Canadian markets can offer; the grading system brings the producer and consumer much nearer together. Under the Canadian Co-operative Wool Growers Company, the sheej raisers of Canada have an organization all their own which is already strong enough to protect their interests in every detail.

CLOVER SILAGE

Red clover is gaining in popularity as an ensilage crop in British Columbia. Generally speaking, it is a safer crop than corn, is easier on the land, requires less labor in growing, and the average yields compare very favorably with those of corn, when the land is prepared with equal care.

The silo furnishes insurance for the clover crop in wet weather. A greater amount of more succulent feed, with les swaste, is obtained by ensiling the crop rather than curing for hay. Good ensilage cannot be made of clover after attempts to cure for hay have failed. Partially spoiled clover makes very inferior ensilage.

Clover i sready for cutting when the maximum bloom is reached. It is best cut in the morning when the dew is on, raked at once, and only as much cut as may be ensiled during the day. If it wilts rapidly better results are obtained by adding water. It should feel wet as it falls from the blower. The cutter knives should be kept sharp and set to cut approximately half inch lengths, as the clover packs more closely and is much more easily removed from the silo when cut short.

Clover is especially adapted for use as summer silage. It may be put in the silo in June and thus utilize space which would otherwise be empty. No waste occurs on the surface if feeding is commenced at once.

Analyses of corn and clover silage made from last year's crops show clover higher in nutritive value from the standpoint of protein content. Practical feeding experiments indicate clover to be equal to corn or milk and butter production, but the latter is a trifle more palatable.—W. H. Hicks, Officer in charge, Experimental Farm, Agassiz, B. C.

THE FIELD CROPS COMPETITION

In our last issue of the Maritime Farmer we published the regulations governing Standing Field Crops Competitions in New Brunswick for the season 1918.

Nova Scotia and Prince Edward Island also conduct Field Crops Competitions.

Undoubtedly the farmers who have taken part in these competitions in past years have a pretty fair idea of the kind of field the judges like to find when they visit their farms. The farmer who pays special attention to production of good seed grain will find ready sale at remunerative prices for all the seed he can produce. It will pay any farmer to specialize in the production of grain for seed and place it on the market, even if he has to purchase the feed grain required on the farm.

Field Crops Competitions are primarily inteded to stimulate the production of good seed which in its turn is responsible under favorable conditions for high yields in the general crop.

It will be well for the farmers who are entering the Field Crops Competitions this year to heed the following advice given by the Dominion Cerealist in the July number of Seasonable Hints under caption "Rogueing of Fields of Grain."

Rogueing of Fileds of Grain

The verb "to rogue," meaning to remove foreign or undesirable types, has not yet come into general usage, and the operation to which it refers is perhaps still less known. The high standard of purity set for seed grain disposed of from the Dominion Experimental Farms makes it sometimes necessary to rogue quite large fields, even up to twenty or twenty-five acres in extent, but such an extensive operation is not advisable for ordinary farmers or seed growers. Nevertheless, eve nin these times, when the cost of labor is so high, **many farmers who expect to sell part or all of their grain crop for seed purposes cannot afford to neglect altogether the rogueing of some of their smaller fields.** In the threshed grain, it is practically impossible to separate barley from wheat an dquite impossible to separate barley from oats. In a field of wheat or oats, however, when the barley has headed out, it is a simple matter to remove all the plants, provided, of course, the seed sown was not very seriously mixed.

If the principal fields which the farmer is growing are too large to be rogued, a wil generally be the case, the smaller multiplying fields (which usually consist of only about one or two acres each) should be gone through carefully two or three times at intervals of a week or more, between heading and harves, in order to remove all plants of other kinds of grain and any abnormal plants observed of the variety which was sown.

If the seed used by the farmer was pure as to variety, there is usually no need to attempt any form of selection. Any very unusual or peculiar heads which are observed should be removed: in other words, the grower should devote his attention to selecting out and rejecting everything abnormal found in his field. This is a much more hapid and, in some ways, even a better process than the laborious plan of picking out the seed which is to be retained.

By rogueing, every year, the special small, multiplying fields of pure seed, which every grower should have, much time and waste of good seed can be avoided when cleaning the threshed crop in the fanning mill, and the higher degree of purity of the seed grain which the grower will be able to offer for sale will enable him to command a higher price.

The hand picking of a few bushels of seed grain in the winter months is desirable, but this operation cannot altogether do away with the necessity for very careful inspection and occasional rogueing of the smaller fields in mid-summer.

METHODS OF CURING HAY

Hay making, or the curing of the hay crop, is an important process in farm work. This year extra help will be required and the hay-field will be the parade ground where many of the "S. O. S." boys and other recruits for Canada's second line of defence will "fall in." Making hay has always been hard work. Improved methods cannot do away with some of the heavy features of the work, though modern machinery enables a man to save more hay during the short period that hay is at its best than when the scythe, hand rake, fork an dtruck comprised his haymaking equipment.

The man in charge of hay making operation should **have experience, plenty of common sense,** and a knowledge of the fundimental principles of weather forecasting if he would conserve all the food value in the hay crop. All methods have to be adapted to the weather and the maturity of the crop. If the old adage was followed, "Make hay while the sun shines," with the present supply of labor much of the crop would be injured by overmaturity.

Some curing methods suggested are:

(a) Mature timothy and other grasses may be cut in the morning of a bright day after the dew is off, tedded, raked in the afternoon, and loaded from the winrows. This hay stored in a tight mow and salted saves in good shape for horses.

(b) Timothy and mixed hay, cut after the dew is off, at the best stage (when in bloom) should be turned, or tedded, raked in the afternoon, and built into large, carefully-made coils. Such hay will make rapidly in coil. Caps are used during threatening weather. Shake out coils to sun and wind, and haul in as soon as the hay rustles nicely. Stor as (a).

(c) Clover hay ,when an average crop or as the bloom goes off, may be cured as described under (b), except that the coils should be made smaller and the clover left in them for a longer time to cure. Caps are neccessary for bad weather.

(d) Heavy clover hay cut during the afternoon or evening receives very little injury from dew or rain if the leaves have not wilted. When it does wilt in the bright sun or wind it should be tedded or rolled over with side-delivery rake until dried out, then cured in small coils as escribed in (c). If clover gets too dry many of the most valuable leaves are lost.

(e) **During continued bad weather** the following English method might be tried with heavy clover hay. Cut when wet with dew or rain; rake at once, haul and stack while wet. Tramp the outside of the stack or rick solid with a horse until you practically create silo conditions. Let it settle, build on again and top it off with straw or grass hay.

Hay caps may be made from A. 1 sheeting cut into 40-inch squares, with a quarter-pound weight to each corner. Each cap will protect 75 pounds of hay.

POTATO YIELDS ON CLOVER VS. TIMOTHY SOD

Clover sod furnishes ideal soil conditions for the potato. It is easily worked into a fine tilth, and the mechanical condition resulting is particularly suitable for this crop, in that the soil is well filled toa good depth with decaying roots which make it yielding and open, but at the same time retentive of moisture. The timothy or grass sod on the other hand does not contain fibrous roots toa very great depth, may be more difficult to prepare, particularly if an old sod, will not give as suitable moisture conditions and undoubtedly contains less nitrogen.

One of the advantages of a short rotation is that the shorter the period the land is down to grass, the more easily can it be prepared for a hoed crop, and if the clover has made a strong growth, there is much more fibre in the soil from the roots in the one year than there is from the timothy for the same period. The older the timothy sod the more vegetable matter, or fibre, will it contain and the tougher it is, hence the practice of ploughing such sod early in the fall and working it dow nso that the sod may rot to facilitate proper working the following spring.—W. S. Blair, Superintendent, Experimental Station, Kentville, N. S.

SOILING CROPS vs. SILAGE FOR THE DAIRY COW

Good pasture grass is the ideal feed for the dairy cow, but it is not available more than a few months in the year. The same objection holds true with all soiling crops. The silo enables us to feed dairy cows succulent feed the year round, and preserves the fodder in a better condition, and with know.

Silage—Less Labor.—There is of necessity much labor attached to preparing the ground, planting, raising, and harvesting the common crops used for soiling purposes. The silo not only saves the labor and inconvenience in the sowing and cultivating of small patches of different kinds of crops, but also in the harvesting at short intervals during the season.

Silage—Less Waste.—There is usually much loss in being obliged to feed the soiling crops before they are mature ,and after they are over-ripe. For the dairyman who has the capital the most practical method of all to provide green feed for summer drouth, is to use a silo. Silage makes use of all weeds, harvested with the crop, for feeding purposes.

Uniformity.—The silo furnishes a feed of uniform quality, and always near at hand, available at any time during the entire year.

..Storage.—The silo permits the saving of crops in years of plenty for the other seasons of poorer crops. Our silos were filled to capacity last fall, consequently some corn silage will be saved for next year's use, which, from present indications, will be very acceptable.

Feeding Value.—The average results from two trials carried on here, indicate silage to be superior to green peas and oats fed as a soiling crop. When fed silage the cows produced 1.65 pounds of milk and .0215 pounds of fat more per cow per day than when fed the soiling crop.

RECEIPTS FOR FARMER SUBSCRIPTIONS

The Maritime Farmer, instead of giving you one receipt in the year for a paid subscription, sends you 24, or one every two weeks. You will find it on the GREEN COLORED LABEL on which your address appears. The date printed thereon is that on which your subscription terminates. If on payment of your subscription the date is not changed within two weeks, please notify us. No other receipt will be sent.

JULY 9, 1918.

DATES OF ISSUE.

July	9-23
August	6-27
September	10-24
Octoebr	8-22
November	5-19
December	3-17

STICK TO THE DAIRY COW

The outlook for the breeders of purebred dairy cattle looks very bright. That it would not be wise for them to always anticipate the same high level as this kind of stock is selling for, today, at the same time prices may be expected to remain as high, comparatively, as they are at present. What will be the level of prices on any kind of produce after the war no one can safely predict. That there will be a general depression seems almost certain. A readjustment without many incidents and extremes is most unlikely and if prices of foodstuffs are a great deal lower than at present there need be no surprise; but whatever takes place, one thing is certain, milk as an economical article of food will hold its own in the face of all disquieting conditions. The dairy industry because of its importance in sustaining the farm balance between cropping and fertility and because of its peculiar and almost indispensable qualities as an article of food, will be the last to go down under pressure and the first to come back with the incoming tide.

Stockmen generally claim that because of the depleted herds in Europe a great demand for purebred cattle will be coming to America—both the United States and Canada. This may or may not be a safe prediction. Just what influence the bankrupt conditions of these countries will play on the return to normal times remains to be seen rather than to be prognosicated. Many supposedly wise men have gone far afield in their predictions of world affairs, during the last three and one-half years, and many more that are in the air are destined to a similar fate, and whether or not this great European demand will pan out or not according to anticipation will yet remain an unsolved factor as regards the outlook for pure-bred dairy cattle for many months, perhaps even years.

In the midst of uncertainties, however, some things remain sure, and one of them is the fact that dairy produce will always be in demand. Other industries crop up now and then and for a little while seem to overshadow the faithful cow, but sooner or later she emerges from under the cloud more illustrious than ever and continues her course in life unmoved by her adverse experience, as though nothing in the world mattered so long as she kept her place "in the sun," and produced the best food to be found for the race and especially for the children.

The experience of the past has demonstrated that the dairy cow is the best proposition on the farm. Those who have pinned their faith to her, and who, through thick and thin, through evil report and good, have given her a reasonable opportunity to make good have not failed. More notes have been met, more mortgages lifted, more barns built and more homes made comfortable and happy through her influence and stability than through any other medium on the farm.

Will she fail now in her country's peril, when good food is needed as never before and when it will be needed in large quantities for all time in the future? If she fails nothing short of national disaster would be the result. No, she will not fail, and the man who remains on her decks will ride safely over the billows of financial disaster that may threaten or even shipwreck some other lines of agricultural interest and reach the port with his colors still flying.

FARM CHORES MADE EASY

There are many little improvements that might be made on the farm that would add to the efficiency of the farm management. For instance, the watering trough may not be placed near the barn. It may mean that it takes three minutes longer to water the horses. Yet when the horses are watered three times a day, th farmer loses practically ten minutes. In a year this would amount to sixty hours or six working days of ten hours each. A fewer number of days would be required in piping the water to the barn and this would make it more convenient and increase the efficiency of the farm ever after. A gate may be off its hinges and have a wire for a latch. These are little matters that could be quickly remedied but neglected they necessitate extra time and trouble in opening and closing the gate every time it is used, and if the gate is near the barn it may be used many times a day. Look after these matters and make the necessary changes to increase the efficiency of your efforts.

MODERN FARM HELP

The farmer has many splendid helpers these days. It would be difficult to determine just which one of the modern inventions and machines are the most useful to him. Is it the tractor, the automobile or the telephone? What would the farmer do without the telephone? By its aid he is brought in touch with the outside world. He is no longer isolated from his fellowmen but by the simple turn of the wrist is brought within speaking distance of every other person who has a telephone even though they are many miles away. What this has meant to the farmer and his family no one can ever estimate. Then the automobile. It has brought every farmer closer to town and to every other farm. Distance is no longer of much consequence to the farmer who owns a car. He can go and come as he will and his family has advantages that their ancestors never even dreamed of. Finally we have the iron horse to relieve the farmer of many heavy labors and enlarge the scope of his operations. Truly the advantages of the present-day farmer are many.

SIRE IMPORTANT FACTOR IN DAIRY HERD

The economical production of milk is possible only when the machine used, the cow, is an efficient one for the purpose and when the person in charge knows how to manage the machine. A cow is born with a certain natural ability to produce milk if given proper conditions. The extent of this ability is mostly a matter of heredity or breeding. The high producing dairy cow is not the result of any special manner of raising the heifer calf. The most skilled feeder cannot put this quality into a cow born without it. All the good feeder can do is to make full use of the ability to produce milk which the cow has inherited. The extent to which this milk producing ability is inherited varies greatly, as is well known. Even in the well bred dairy herds not all the heifers raised prove good enough to retain in the herd. Constant culling of inferior cows has been found one of the most important measures in maintaining a profitable herd.

The ability to produce milk is inherited through both dam and sire, but since the sire is responsible for half the inheritance of each young animal, he is clearly the most important factor in improving the herd, according to C. H. Eckles of the Missouri College of Agriculture. If the cows in the herd are capable of producing only 200 pounds of fat a year and the sire used represents a breed or family, the cows of which average 350 pounds of fat a year, it would appear reasonable that the heifers would average halfway between an increase of 75 pounds of fat a year.

ADVERTISING IS VITALLY IMPORTANT TO ANY INDUSTRY

As a potential force in the promotion of business enterprise, advertising has come to be looked upon by the closest analysts as of primary importance. Its first purpose is the dissemination of information, and its second purpose is to stimulate action. These are the two factors which usually enter into business transactions. Advertising efficiently done is simply a proces sthrough which these two business elements are speeded up.

Looked at from this viewpoint anyone will admit that advertising is of vital importance to industry. It justifies the careful thought and consideration of both the seller and the buyer. If its full purpose is accomplished both parties to business transactions stimulated by it profit through it. And the fact is well known to all of us, when once we stop to think about it, that there is scarcely any business action nowadays that is not influenced in a greater or less degree by advertising.

In spite of its indispensable potentialities in business there are those who fail to recognize advertising as a justifiable business force. They would place it in the list of non-essentials, little heeding the fact that the removal of any potential force from the conduct of business makes for inefficiency, lost motion, and consequent increased cost.

Those who rail against advertising are rowing against the stream: Those who recognize it in its true light travel with their faces to the fore.

HERD'S BETTER HALF

The sire is half the herd. There is usually one sire for every twenty to forty females, hence the characteristics of the male are inherited by from twenty to forty times as many animals as those of a given female. Efficient sires are those bred for a particular purpose and are thus able to transmit to their offspring the characteristics for which they have been bred.

NEW BRUNSWICK COMING TO THE FRONT IN SHEEP RAISING.—DOG TAX REDUCES NUMBER OF CURS

(Continued from page 613)

ists. Dr. S. W. McClure, secretary of the National Wool Growers' Association—range sheepmen—says that for 1918 we have more on hand than we shall need. But the rub comes when we attempt to get the fleeces in sight in hand—if we can speak of wool in Australia or Argentina as in sight.

"Doctor McClure figures on 100 pounds of wool as the annual clipping ration of an American soldier. A recent estimate from a member of the Shipping Board who has been working on the problem of cargo space says 190 pounds will be the yearly consumption of a fighting man. We also have a Navy, and we are going to have a very big Army unless William decides soon to save his from destrustion. So no matter if we should be safe for a year, it is probably a good thing to become alarmed over the wool situation. The fact that the Government has taken charge, reluctantly we may be sure, nad has decided to cut out the few former frills on Sammy's suit, cinches the argument of necessity.

"A good deal of bunk has been passed out regarding sheep. The man who does not raise them has been taught to believe that they need not be watered, which is true if dew falls regularly or the vegetation is succulent. He has been assured he can turn them out and not bother about them until lambing and shearing time, if dogs and disease do not attack them. A lot of sheep are handled that way, and that is one of the prolific causes of failure with the flock on the ordinary farm.

"Sheep can be handled with less care than any animal on the farm. They will eat the cheapest sort of roughness, which tallies with the national need to save grain, and they are fed at the expense o fless human labor than other animals. If they are only given an occasional inspection, and treated as a side line should be treated, they will prove a profitable investment to the average farm. Like the farm poultry flock, which is the main dependence of the country for eggs, the farm wool and mutton flock will easily provide for the needs of the United States, and the farmer needs to give it even less attention than his wife gives her side-line business.

Slowing Down with Sheep

"The farmer who starts in with a few sheep and gives them half attention is usually surprised at the rapidity with which his flock increases and at the profits which seem to come without expense and with very little labor. I know men who have passed the age when they can buffet the active life og grain production, who have slowed down with sheep and made a better living than before.

"These are facts the Government is urging. Aparently the turning point has been reached in the much-harassed sheep industry. The great Western range country, the land of golden fleece, has probably passed the period of maximum production. The free lands are being settled up and the big producers are cutting down the size of their flocks. The places to turn to are the farms of the Middle West, the North, the South, the East and the cut-over timber lands. In some of these sections, notably Ohio, Michigan, Pennsyvania and the Eastern States, sheep once enjoyed great popularity. The competition of the newly opened West, the depredations of dogs and politicians, and especially the fear of dogs came pretty near giving them a knockout. But the wheel of fortune has at last brought the farmer a chance.

"Sheep are profitable almost anywhere these days—if they live to be shorn or slaughtered—and will continue to be good property for a long time, in view of present world conditions. Without considering wool, the price of which will no doubt be good for years, we have a good actual mutton market and a big potential market that can be developed.

"In 1900 we had 0.8 sheep per capita. Last year the proportion dropped to 0.56 per capita. In England mutton makes up 21.8 per cent of the meat diet. In this country only 3.78 per cent of our meat ration comes from the sheep. The British farmer raises sheep on small farms and apparently makes a go of it. He has no big and cheap ranges. He has intensive methods and he protects his flocks.

"According to an investigation made by men from the Office of Farm Management of the United States Department of Agriculture, the cow was more profitable than the sheep on New England farms just previous to 1916. But a big change has occurred. Now the sheep is the better profit producer. An animal unit of sheep—seven head—makes $33.18, while a cow—one animal unit—makes on the average only $12.72. Evidence from various farming sections approximately corroborates these figures.

"In 1913 an estimate made by the crop reporters of the United States Department of Agriculture showed that in thirty-six farming states the number of sheep could be increased by 150 per cent without displacing other livestock. That would mean 34,000,000 more sheep than those states now have. Fourteen hundred and eleven farmers were asked if sheep were profitable in the farm states and 887 answered "yes." If taken to-day the vote might be an unanimous affirmative, with one qualification—if dogs do not interfere.

"The great enemy of the flock outside of the range country is the uncontrolled dog. Of 894 answers to the question as to causes preventing increase in sheep production 531 replied "Dogs."

"The actual destruction that can be laid at the door of the dog kennel cannot be measured, but we can get near enough to ruin the wandering cur's reputation as a law-abiding friend of man. Reports from 502 counties in states of the East and Middle West show that 34,683 sheep were killed in one year out of flocks aggregating 6,836,492. Figuring on this basis the farm states probably lose, at the lowest estimate, considerably more than 100,000 sheep each year to the night-prowling cur.

Since July first of last year dogs have killed 3500 sheep, forty head of young cattle and seventy-five hogs in New York State. In the flocks chased or worried there were 20,000 sheep, and every farmer knows what a dog raid does to the survivors. The total damage is estimated for the year at round $100,000. So far nearly 300,000 dogs have been enumerated under the new law, but it is probable that there is still a large number unlisted.

"The dog population, in spite of laws requiring a tax and a license tag, will always be a thing to guess at, like the number of cats or rats in the country. Property that has no particular value is not very carefully accounted for, especially when it means expense to the owner. However, various estimates have been made and a favorite figure is 10,000,000—10,000,000 dogs!

"Estimates of the cost of keeping these dogs vary from nothing to fifty dollars a year each. A Mississippi farmer says that since the war, dogs have been more destructive than ever because the garbage can now supplies poor picking. Rather than starve many a homeless dog has beocme a killer.

Althouh the average canine is pretty near useless, it would be foolish to contend that all dosg or most dogs should be killed, even though they do consume a lot of food that might go into the making of edible meat. A man will have his dog and he will fight for him, just as a dog will often fight for his master. But the dog lover should help in the campaign to control or exterminate the sheep killer.

"No man of good sense who is really interested in the dog will object to this. Still we find that there are a lot of fanatics who froth at the mouth like some of the unfortunate animals they think they are defending from unjust laws. Strange to say, many proposed dog laws have failed of passage or have had their teeth pulled on account of the objections raised by misguided humane societies. Ohio failed to get a really good law on that account. The idea seems to be that it is cruelty to kill off dogs, even though they pay no tax and are allowed to run at will. If these well-meaning but short-sighted persons could see the results of a dog raid on a flock they might change their attitude. The dog once started on his criminal career becomes a canine Hun who delights in frightfulness. He does not kill for the sake of appeasing his hunger, but he will kill or maim dozens of sheep for the fun he gets out of it.

"This form of destruction is only the first count against the wandering dog. He is guilty of carrying diseases and parasites of livestock. In the recent disastrous outbreak of foot-and-mouth disease dogs were frequently the means of spreading the infection from farm to farm. The sheep raiser should find an ally in the hog grower, for the dog is an active agent in spreading hog cholera. But he is most dangerous to humans when he is affected with rabies. The State Hygienic Laboratory of North Carolina reports that from 1912 to 1917 1503 people were treated, and that in nine years 1217 rabid dogs were examined. In Massachusetts 164 persons were bitten by mad dogs in 1917. In New York State in one year ending June 30, 1917, fourteen general and 271 individual quarantines were placed on account of the presence of this dangerous disease. It is always the uncontrolled dog that does the damage.

"In spite of all the evidence pointing toward the necessity for stringent dog laws the sentimentalists are found in the opposition. They quote, not actual facts, but Senator Vest, or Pudd'nhead Wilson, who said: "If you pick up a starving dog and make him prosperous he will not bite you."

"Missouri, the state that sent Vest to the Senate, produced the cur's "national hymn." It was a weird thing, with about as much music and life as a coon dog's baying on a cold trail, but it represents a state of mind!

Every time I come to town
The boys start kickin' my dawg aroun' ;
Makes no difference if he is a houn',
They gotta quit kickin' my dawg aroun'.

In the legislature of one of the Southern States a preacher started his opposition to a proposed dog law in this strain: "I am the dog. God made me. I am the friend of man. My habitat is the earth."

"A pro-sheep man who knew somewhat of psycholoy met the "argument" with this knockout: "I am the flea. God made me. I love animals. My habitat is the dog."

Foolish talk? Yes. But this foolish talk is proof of the place the dog has in man's affections. We all like the dog and will certainly not exterminate him. He has been useful to the farmer and the flock-master from time immemorial. Now he is saving hundreds of lives on the battlefields with the fidelity that is a marvel to us humans. Such dogs have no enemies.

"It is the "bad egg" among dogs that needs to be controlled by law—to be destroyed if he is not worth the tax and attention to keep him out of mischief. A famous old Illinois sheep raiser expresses his feelings in a letter. "So far as I can see," he says, "no dog law has been made to keep curs from killing sheep. For year I have taken the law in my own hands and I kill every dog I see on my farm and will give anyone a dollar for a dead dog killed on my place. My idea of a good law is one that will make a man keep his dog under control, and to punish by imprisonment a man who does not observe it. Fining offenders a few dollars does not keep the dog up nor save sheep."

"A New Englander who has had experience with the shortcomings of the law says: "The vagrant dog is of great and growing importance. We have at hand a big source of wealth for the farmer and of cheap meat and wool for the nation. The hillsides of New York and New England could be stocked with sheep if we would but permit it.

"This cannot be done, however, while we permit the vagrant dog to roam at will. We do not ask that dogs should be destroyed. Governor Holcomb, of Connecticut, is reported to have said that if three-quarters of the dogs in the state were killed the sheep industry would revive, to the great advantage of the state. It should be possible to kill off the wanderin, homeless curs, but we do not ask even that.

"We ask that dogs should not be permitted to run at large either by night or by day. Those who want dogs should keep them under their control. There is no other protection for sheep. The expense of a shepherd with a small flock is prohibitive and dog-proof fences are too expensive.

"At a time when the world is short of food and when we have not half a supply of domestic wool for our own mills, is it too much to ask that the lovers of dogs should keep their pets at home?"

"During the past year there was a lot of agitation for a Federal law putting a tax on dogs. So far no such legislation has received much consideration. Even the plea of a wartime need for revenue did not stir up any enthusiasm. Perhaps it is just as well, for, although a Federal law might have a good moral effect on the states, state laws will always be necessary to handle the problem. Uncle Sam is not equipped to act as dog catcher.

"But state laws must be improved if we are going to have the raw materials needed for our industries and to cover our backs. If the war lasts much longer the dog is going to deprive the soldier of a suit that would protect him from pneumonia.

"A few of the state legislatures, notably in Pennsylvania and New York, have in the past year passed laws that already are having a decided effect in putting sheep raising on a new foundation. If every state had a law as thoughtfully planned as Pennsylvania's there would be some hope for the farm flock. Some legislatures, Kentucky's for one, have already copied it.

"This law provides dogless nights, for it makes a night-prowling cur an outlaw, and every canine six months old or over without an up-to-date tag is in danger of a death sentence wherever he is found. A new license must be obtained by January fifteenth of each year, and the fee is not less than one dollar nor more than two dollars for each male and not less than two dollars nor more than four dollars for each female. The exact amount is left to the discretion of the county commissioners.

"Anyone can enforce the law if he catches a dog chasing, worrying or wounding livestock. If he kills a dog, tagged or untagged, under these circumstances he cannot be held liable for damages. Tagless dogs that enter fields can be killed by the owner or tenant or by his agent or servant. Police officers are required to seize and detain dogs with tags that are unaccompanied by their owners or keepers. They must kill every dog without a license. For failure to do his duty a police officer is liable to a fine of two dollars for each offense. On the contrary, when he detains or kills a dog he receives a reward of one dollar. It pays the men to do their duty.

"Fines and licenses go into county funds and payments for damages to livestock are made directly from this fund. In New York the money has to be paid itno the state treasury and is paid out from that source, an inconvenience and a cause of much delay. Under the Pennsylvania law a man

HORTICULTURE

POTATO SPRAYING

By G. E. Sanders, Dominion Entomological Laboratory, Annapolis Royal, Nova Scotia.

Of all operations conducted on the farm it is probable that spraying potatoes is the most profitable. In fact, when one considers that the increased crop is due to spraying one acre of potatoes at a cost of about $15, is about 100 bushels it becomes apparent that probably the operation or investment that can be relied upon to give the greatest returns, of any open to farmers at lest, is potato spraying. It is equivalent to buying potatoes at 15 cents per bushel and it is more than probable that the price of potatoes will be more than ten times fifteen cents during 1918-19. Experiments carried on by the laboratory staff on the school plot at Annapolis in 1917 show that an acre of potatoes at the height of the grwing season will store about 5 bushels of potatoes per day. The potato being mostly starch, is made up almost wholly of materials that are gathered from the air by the leaf and not of materials taken from the soil. As soon as the top dies the storing of starch in the form of potato tubers stops. Unsprayed potatoes are likely to be and usually are attacked by potato blight when the normal crop of tubers is from one third to one half stored, and as soon as the tops are killed by the blight the storage of tubers ceases. Spraying with Bordeaux will protect potato plants absolutely from blight and will result in a normal season in keeping the tops green from ten to fifty days longer than normal. Keeping the tops green for only three days will result in 15 bushels more potatoes per acre or more than the value of fifteen dollars, and fifteen dollars will spray an acre fou ror five times, cost of labor as well as materials included.

In view of the shortage of food and the probable scarcity of potatoes in 1918-19 it is but litttle short of a crime for a man to neglect the thorough spraying of his potatoes in 1918. Every acre thoroughly sprayed five times means in a normal season one hundred bushels more potatoes, and this year the country needs the potatoes.

Potatoe sshould be sprayed when about eight inches high with a poisoned Bordeaux mixture, repeat every ten days or two weeks until the tops are done growing. Make sure that all parts of the plant, the tops and undersides of the leaves and the stems are thoroughly wet with the mixture.

To make Bordeaux mixture—dissolve 4 pounds of bluestone in 20 gallon of water and slake in another barrel 4 pounds of stone lime, making it up later to 20 gallons of milk of lime. Pour the two by alternate buckets into the spray barrel and add the poison. In using hydrated lime, dissolve 4 pounds of copper sulphate or bluestone in 40 gallons of water and 5 pounds of hydrated lime stirring rapidly all the while.

As a poison one can use any of the following, they being arranged in order of value, present prices considered. To 40 gallons use—

- 1½ lbs. arsenate of lime powder.
- 2 lbs. crystal arsenate of soda.
- 1 lb. fused arsenate of soda.
- 1½ lbs. arsenate of zinc powder.
- 4 lbs. arsenate of lead paste.
- 2 lbs. arsenate of lead powder.
- 1 lb. paris green.

LARGE INTEREST IN BEEKEEPING.—VIGOROUS CAMPAIGN TO CONTROL AND ERADICATE DISEASES. — DEMONSTRATIONS BEING HELD

At one time large crops of honey were harvested by bee-keepers in the lower part of the province, but during the last few years a large decrease has been notetl in the number of colonies of bees kept there. This decrease has been due in some cases to poor wintering but in others it has been caused by disease.

The American Foul Brood has been known to exist in that part of the provice for a number of years but with the exception of one or two cases, no effort has been made to control or eradicate it.

The provinces of Ontario and Quebec are vigorously fighting this disease the treatment of which is very simple, and when thoroughly carried out, effective.

With the object of acquainting the beekeepers with the apearance and symptoms of this disease so that they may detect and treat it, the Department of Agriculture, through their Provincial Apiarist, is carrying on a campaign for the control and eradication of the disease wherever it exists in New Brunswick. During the past few weeks nearly every apiary has been inspected in the districts where the disease has been known to exist, and the disease was definitely located in four different districts.

On June 18th and 19th, Mr. L. T. Floyd, Provincial Apiarist, assisted by Mr. C. B. Gooderham, Asistant Apiarist, Ottawa, visited a large number of apiaries an dinsjected more than 50 colonies of bees. On the afternoon of June 19th they held a demonstration in the apiary of Mr. Daniel A. Coates, Corn Hill, a large number of interested beekeepers being present. Mr. Floyd spoke on the opportunities for beekeeping and was followed by Mr. Gooderham, who talked on the different diseases effecting bees, demonstrating the treatment of the diseases by the use of affected colony. He stated that the disease germs were carried from hive to hive by the robber bees and in this manner the disease sprea dfrom colony to colony and from apiary to apiary. As the disease developed and increased the colony gradually diminished in numbers until all the bees were gone and their honey was left to be carried away by bees from healthy colonies. Mr. Gooderham also demonstrated the most approved methods of treatment for the disease and this was followed by a discussion of beekeeping work in which a number of the most prominent beekeepers took part.

Mr. Floyd invited those present to become members of the Beekeepers' Association which now has a membership of 83 and is doing good work in the interests of the industry.

The Department is able to report a large interest throughout the province in beekeeping work this year and the names of 400 different beekeepers are now on its mailing list.

It is planned to hold similar demonstration and field meetings in different localities throughout the province and announcement of the dates will follow in due course.

THINNING OF FRUIT

More attention is being given to the thinning of fruit than was customary a few years ago. Two main objects are being sought:

1st.—To produce fruit of a good size, perefct in shape and colour.

2nd.—To maintain sufficient fruit spurs vigorous enough to produce a full crop the next year and thus eliminate the "off year" habit of our trees.

After the June drop is over, inspect the trees and those with the heaviest crop on thin first. A tree bearing a full crop thin to one fruit to one spur. If the spurs are too close cut all fruit off every other spur. This leaves every second spur barren and able to store strength and vigor to produce fruit next year. When a tree has only a light crop two fruits may be left to a spur. The advantage of the single system is that the fruit does not get damaged by two specimens rubbing and knocking together in the wind. Start thinning as soon as you are sure that the imature fruit has fallen, and go over the trees twice at least. Thin apples 5 to 6 inches apart; apricots, large varieties 4 to 5 inches, small varieties 2 inches apart; peaches 4 to 5 inches, and pears 4 to 6 inches apart according to variety. In thinning apples and pears better results can be obtained by cutting the stems with small shears; otherwise there is danger of impairing the hold on the spur of the remaining fruit.

HERE'S
The MACHINE
that will
HARVEST
every bushel of
that BUMPER
CROP
The Frost & Wood Binder is the Product of modern engineering skill applied to the experience gained in making good Farm Machines for almost 80 years.

It really describes---

You know how important it is to your success as a farmer that you select the right Binder. You can't do it from the brief description in any one advertisement, but you can go a long way towards it from reading the above up-to-date, fully illustrated pamphlet.

It tells you all about the Frost & Wood Binder—why it is built to give better service and harder service—why our 80 years' experience ensures that it has the strength and ability to get your crops in without fail.

FROST & WOOD BINDER

Powerful Drive Wheel	Different Cutter Bar	Special Relief Roller
Roller Bearings	Flexible Grain Wheel	Sure Knotter
Special Power Frame	Positive Elevation	Fine Sheaf Carrier

Be sure to get a copy of the above Binder Booklet from your nearest Agent or write to-day to our nearest Branch

SUMMER PRUNING OF FRUIT TREES

The summer pruning of fruit trees should only be applied to young trees that are making too much dense growth and not sowing signs of fruiting. We must remember that the leaves are the lungs of our trees, and if too much foilage is taken away, too severe a check is given the tree. The main abject of pruning in summer is to allow light and air to circulate freely through the centre of the tree and thus allow the fruit buds to mature and bear well developed fruit of good color and quality. To obtain this, cut back the side shoots and thin out the heavier growth at the top end of the main branches, taking care to leave one or two main shoots to carry on the building process of the tree. Do not cut these back. Start summer pruning as soon as you notice that the trees are getting too shaded at the centre where the bearing surface of young trees should be. Summer pruning is intended to develop and strengthen fruit buds rather than force leaf buds into fruit buds; this is borne out by the fact that the change from leaf to fruit buds takes place before summer pruning would be started. Thin out the tree a little at a time and go over them oftenr rather than defoliate heavily at one time. Air and sunshine not only increase quality and quantity of crops, but tend to keep away disease and maks handling and harvesting easier.JR. H. Helmer, Superintendent. Experimental Station, Summerland, B. C.

CARE OF THE POTATO CROP

If the potato beetles have not been all killed by the time this reaches the reader, there should be no delay in

PEDLAR'S GEORGE SHINGLES

Lightning-Proof

THESE shingles lock on all four sides, forming practically a one-piece roof of heavily galvanized steel, which, when properly grounded, causes lightning strokes to be evenly and harmlessly distributed. Proof also against fire, wind, rain or snow, and will not rust or decay, but will last a lifetime without need of repair. See your dealer or

poisoning them. Anything which injures the foilage will lessen the crop; hence the leaves should be kept as free as possible from injury caused by insect or disease. A mixture of eight to ten ounces of Paris green and three-quarters of a pound of powdered arsenate of lead, or one and a half pounds of paste arsenate of lead to 40 gallons of water has been found more satisfactory than either poison applied separately. As the late blight may attack the plants any time after the first week of July, it will be desirable to make the first application of Bordeaux mixture with the last spray for bugs, and the two may be applied together. The formula for Bordeaux mixture is: 6 lbs. bluestone, 4 lbs. lime, and 40 gallons water. While the late blight does not appeare every year, it has been found very profitable, on the average to spray for it every year. In a three-year experiment at Ottawa there was an average yealry difference of 94 bushels yer acre in favor of spraying.

The tops should be kept well covered with the Bordeaux mixture from the time it is put on in July until the leaves dry up or are killed by frost. The number of times that it will be necessary to spray will depend on the season. Four times during the season would be a fair number of times in order to keep the foilage covered, but it might be that even one spraying, if it happened to be applied just before an infection, would save the crop. The aim should be to apply the Bordeaux mixture before the disease is seen, not afterwards.

Deep cultivation in July may do more harm than good by destroying roots and drying out the upper few inches of soil where tubers are forming. If the tops have not already met and cultivation is still necessary, it should be very shallow, or just enough to conserve the moisture. Sometimes hilling up gives better results than leaving the soil level, especially if it is a wet season and the soil heavy. In loose and sandy soil, level cultivation is likely to give better results in all seasons.

Conservation of moisture by shallow cultivation is very important, as tubers will not develop if the oil is dry. If the plants are kept in a healthy condition until the hot weather of mid-summer is over, during which time if the weather is dry few tubers will grow, the grower will be well repaid by the great development of tubers that will take place when the ground becomes moister and the weather cooler.

HEROLD'S FARMS, Fruitland, Ont.
Dept. L Niagara District,

CARE OF THE VEGETABLE GARDE

In order to have crisp, succulent vegetables, growth sould not be checked and, while in seasons which are cool and moist the cultivation or loosening of the surface soil is not si important as in seasons which are hot and dry, it will be found very profitable no matter what the season, to loosen the surface with the hoe or rake after every rain. In dry seasons this conserves the precious moisture, and in both dry and wet seasons it permits the air to enter the ground freely to promote growth.

If cauliflowers do not have an abundance of moisture they will not head well and while melons require great heat for best results, they must have lots of moisture also.

Celery will go to seed if checked in its growth from lack of moisture; hence the importance of keeping this vegetable growing well, which can usually be accomplished by keeping the ground well cultivated. If there is a protracted drought it will be desirable if praticable, to water the celery thoroughly.

The asparagus and rhubarb beds should receive a heavy applicaton of manure as soon as possble after the cutting season is over. Do not wait until spring, as this will be too late to affect the crop materially. Manuring now will help to make strong growth this season, which will mean that good crowns will be built up to furnish stalks for cutting next spring. As a rule, both asparagus and rhubarb are cut later in the season than they should be, with the result that the plants are weakened, the stalks become small, and the maximum crops are not produced from year to year. Neither of these vegetables should be cut after the first of Julqy.—W. T. Macoun, Dominion Horticulturist.

IMPORTANCE OF HILL SELECTING FOR SEED POTATOES WHILE THE TOPS ARE GREEN

Advice on the hill selecting of seed potatoes has usually been to dig a certain portion of the potato crop by hand and as the digger comes to a good hill with from eight to twelve or more well-formed potatotes above two ounces in weight each and typical of the variety, to place the tubers from such hills on one side so that they might be reserved for seed. This practice undoubtedly has led to increased crops, but experience on the Experimntal Farms and among growers who have been following this method has shown that the results were not uniformly as successful as might be expected. The investigation of potato diseases indicates at least one reason why increased yields from such hills used for seed cannot always be depended upon. It appears that such diseases as Leaf Roll, Mosaic, and others of that type, may infect the plant and the tuber without causing loss of yield during the season of infection, while the next year it is possible, and generally probable, that tubers carrying this infection will give an inferior plant and a small yield. It is, therefore, quite essential to select not only hills that give large yield but plants that show freedom from disease, and the only way this can be done is for the grower carefully to examine his potato plants during August or before such time as they begin to ripen and stake the hills which he finds free from such diseases as show on the plants. Then, when digging time comes the grower can go through his field and dig out first all the hills that have been staked. He will probably find that not all of them have large yeilds tf tubers and he will only take those that come up to or exceed the standard which he has set. By this process of double selection, if his work has been thorough, he will secure seed potatoes from healthy, large-yielding plants, which shoulr perpetuate their characteristics in the following crop.—W. W. Hubbard, Superintendent, Experimental Station, Fredericton ,N. B.

Eureka Potato Digger

Gets the Potatoes and pays for itself in one season. Saves extra help

Potatoes frozen in ground last Fall could have been saved by the Eureka. Works in ground and conditions where other diggers cannot.

The Eureka elevator and duplex shaker provide more separation than other diggers. Large wheels and main gears supply ample power. Special construction avoids frequent breakage and lost time. Growers report digging 150 or more acres without repairs. High clearance over shovel prevents weeds and vines bunching. Has vine-turner attachment.

Specially adapted for use with tractors and for engine attachment.

6-ft. and 7-ft. sizes; several styles.
Prompt shipments from distributing points.

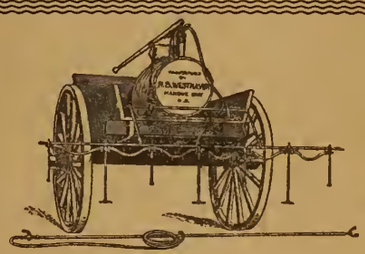
The bug, rust, weeds and rats all are efficient allies of the Kaiser. Get ready to drive them out of the trenches.

Beans and peas are rich in proteins. One pound of dried navy beans contains 1605 calories—almost the equivalent of a pound of wheat flour, 1635—and more than in a pound of round steak, 890 or of sirolin, 975. A pound of potatoes contains about 400 calories parsnips 300, green corn 460, onions 220. Six ounces of potatoes will save 1½ ounces of flour. With potatoes freely used we can get along with less bread.

A Wire Letter Basket is most useful in the kitchen. Baked potatoes arranged in it can be taken out of the oven, turned and put back with no danger of burning the hands. Turned upside down, it makes a fine rack for cooling bread and cake. tI is safer than a waiter in which to carry small pieces of china back and foth between the dining room and the kitchen.

WHAT WILL YOU DO ABOUT IT ?



Spray OR Suffer Loss ?

"Perfect" Spray Pumps are made by

R. B. WESTHAVER, - Mahone Bay, N. S.

DO IT NOW

When a man ain't got a spray pump and is feeling kind of down,
Cause the pesky little insects won't leave his crops alone,
It's a great thing, oh my brethern, for a feller just to say
"Send and get a Perfect spray pump, and apply a coat of spray."

It makes a man feel queerish when the season's work is through
And the tatties are all blighted, and the apples wormy too,
Then order up a "Perfect" and do it right away,
And spray the fruit and tatties and save them while you may.

You'll never find another that does the work so well,
From the strainer up to handle, the outfit works just swell.
It has good agitation, and a real relief valve too,
It throws a spray that's perfect, and what more can it do?

Manufactured by R. B. Westhaver, Mahone Bay, N. S.

DAIRYING.

SUPPLEMENTING THE COW PASTURE.—WHEN TO FEED CONCENTRATES

With coarse grains at abnormally high prices the question will arise in the minds of many dairy farmers as to whether or not it will pay to feed concentrated feeds of any kind on dairy cows while on pasture.

Given an abundance of good pasture, experiments at Macdonald College have proved that, it will not pay to feed the average dairy cow grain. With limited pasture and a summer of extremely unfavorable feather, it will pay to feed milking cows something besides pasture. If soiling crop or silage is available, concentrated feed is less important, but for the best returns from every standpoint a combination of the two is necessary.

The prevailing practice in many districts is to depend upon pasture entirely. For the average cow having as she does small milking capacity and usually quite a territory of rough pasture, it is questionable if grain feeding will pay under present conditions. On the other hand when farming is more intensified, with less acreage in pasture and better cows, it is absolutely necessary and it will pay to supplement the grass when it gets short with at least a limited amount of grain feed.

The time to commence feeding is just when the cows begin or even a little before they begin to shrink because of short pasture. If feed is delayed until the cows have materially decreased in milk and flesh the results from feeding at first will be disappointing and will continue so until the cows regain normal condition. This fact explains many of the apparently poor results from extra feeding.

The amount of feed necessary must depend on the cow's work, her condition, and what else she is deceiving. In the average case three to five pounds of meal per day will suffice. At the present time it is often a case of taking what meal may be available and mixtures are almost out of the question. Oil cake meal seems about as good value as anything and less of it will do. It is a good milk producer and is a splendid feed for sustaining and increasing body weight. If other feeds can be combined with it so much the better, but one pound of it per day even alone on short grass will go a long way in tiding the cows over a bad time.

CAN YOU MILK A COW? DOING THE JOB RIGHT MEANS BIGGER RETURNS

Diarymen are being continually exhorted to "breed, weed and feed," if they would realize the full possibilities of a good cow. Yet, with all this machinery coupled up and going smoothly, the system may not be without its breakdowns. One may practice all the latest intricacies of careful breeding and selection, feed a well-balanced ration calculated to produce the maximum in milk yields, and still the result, as shown in the milk pail be decidedly disappointing. It is one thing to put a cow in the proper condition to secrete a large quantity of milk, but the ability to secure by the actual process of milking, all the cow is capable of producoing is quite another matter; all milkers cannot, or at least do not do it. There's a reason.

The udder of a cow is a delicate piece of machinery and quite as sensitive to abuse or improper handling as a watch. Few dairymen, perhaps, realize this. Hence, to avoid losses, it is essential to know something of its structure and the part it plays in milk production.

It is erroneous to suppose that it is simply a sack into which milk is poured during the day to be drawn off at night. The udder is just one large collection of cavities or milk secreting glands, lined by many epithelial cells or small pouches, and surrounded by a net-work of arteries and veins. Throughout the day these arteries are bringing the various constituents of which milk is composed, such as fats, proteins, water, ash, etc., to the outer surface of these small cavities where the epithelial cells select the material that will ultimately become milk. Along toward night these cells have collected their full capacity of milk-producing elements and holds them available, but there is no milk.

Not until the milker mounts a stool and begins the actual process of milking do the numerous cells in the udder start to give up their contents, which gravitates to the milk cistern in and above the teat. To prevent too rapid flow and also to stop foreign material from working its way upward, the bottom part of the teat is guarded by what is known as the sphincter muscle. The amount contained in the milk cistern at any time rarely exceeds a pint. At first, the water content being less viscid passes through the cell walls more readily and in larger quantities than the solid particles of fat, protein and mineral matter. This explains the reason why the first milk secured is lacking in quality, that is, contains comparatively little fat and other solids. The dairyman, having a fondness for the stable cat has a ready remedy by seeing that his feline friend is liberally supplied from these initial strippings. As the process of milking proceeds, the bulk of the water content is given off, the remaining fluid becomes richer in fat, casein and mineral matter.. It has been found that these last strippings often test as high as ten or eleven per cent., while the first may be as low as one and a half per cent.

Now any dairyman wil have observed that a cow will not always give her milk down readily. This is absolutely notictable when her calf has been but recently removed, when she has been summarily hustled into the stable with a dog hanging to her heels or persuaded to "hist" with a few tatoos of a milk stool in close proximity to her ribs. The milk productive system of a cow is so constructed that she can retaliate automatically, withholding both quantity and quality. In fact no cow will give her full capacity unless in response to nervous stimulation. To do her best she must be in a pleasant mood. Many little things, that are seemingly trifles make a difference in the milk yield and are inevitably portrayed in the milk cheque. For example, one cow objects to whistling, but likes singing, another has opposite views on the matter. Few, if any, to their credit, can be soothed with profane language, while many prefer absolute quietness to any form of entertainment.

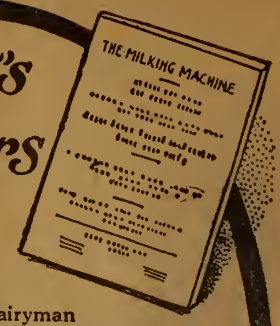
There is no denying the fact that milking the dairy cow is a very important phase of her management. Even many who fully recognize this, have to admit that they cannot get as large yields from their own cows as some of their hired help. Like the production of music or poetry, the expert operator requires to be born such—there is little hope of the manufactured article becoming an ideal performer. At the dairy shows, the writer has watched with a good deal of interest the men who milk the cows that are on test. These men are doubtless selected for this work because of their ability to get the last drop of fat and the last ounce of milk the cows are capable of giving. Invariably, they are rapid and businesslike in their movements. Usually the slow milker is a poor milker and fails to secure the best results. Of course, there are many cows not over-sensitive that will do well with the average man. But the highly nervous cow, often among our best producers, requires a specialist. Such a milker is careful to observe the many little details that appeal to the cow and help to produce a proper nerve stimulation. He will insist on milking his regular number of cows himelf, instead of changing about with the other milker. Moreover, they must be milked in the customary order and at the same time each day. He will also see by careful manipulation that the animal has been milked dry. Carelessness in this respect means considerable loss in succeeding milkings. The man who milks the cow has a greater influence on her capacity than he is usually credited with.

FEEDING COWS REQUIRES TACT OF OBSERVATION

In a manufacturing plant each machine turns out as much of the finished product as it is capable of turning out and to do this it must have the required raw materials in proportion. The dairy cow is in a sense a machine and to a very great degree her output depends upon the feed. But there is another way of looking at it. The amount of feed which may be profitably given the cow depends largely upon her production. The quantity of food must naturally be regulated according to the yield of milk. A cow giving 60 pounds of milk per day requires more feed than one giving 20 pounds per day. Yet there are many herds in which each individual animal gets the same amount of feed regardless of the amount of milk produced.

Like the machine there is a limit to profitable consumption with the cow. If a cow gives three times as much milk as another on the same amount of feed, and cow giving the larger quantity is fed enough to maintain the animal body without loss, the cow giving the lesser amount must make poor use of her feed, must waste considerable of it in indigestion and must be an unprofitable animal to keep in the dairy. Where all cows are fed alike some of the animtls must get an in-

The Government's Advice to Farmers on Cows



In the interest of every farmer and dairyman the Dominion Government has issued a special circular pointing out the value of the Milking Machine under the present conditions of labor on the farm.

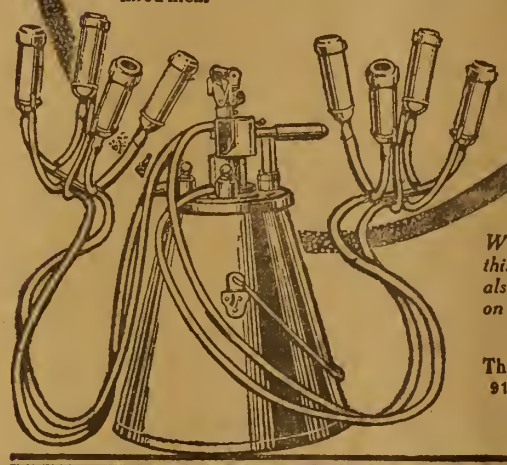
Mr. J. H. Grisdale, B. Agr., Director of the Dominion Experimental Farms says, "The present is no time to let things stand in the way of increased production, and every farmer with a herd of twelve or more cows should seriously consider the installation of a milking machine. Three years' experience of mechanical milkers on the Central Experimental Farm shows that cows do not dry off more quickly than when milked by hand. Cows have no more objection to being milked by a milking machine than to being milked by hand."

The experience of an ever increasing number of farmers, backed by the opinion of the leading Experimental Farms and Stations prove that

EMPIRE MILKING MACHINES

increase production and save money and time, one machine doing the same work as three hired men. On account of its simplicity, a boy or girl can operate an Empire with ease—doing the work with uniformity and without injury to the cows.

You can help the cause of the Allies by keeping and enlarging your herds despite the shortage of labor. Empire Milking Machines will do the milking for you, cheaper and quicker than hired men.



Write us for fuller information on this important subject, and learn also how to do away with drudgery on the farm.

Lock Drawer HC 20 HAMILTON, ONT., CAN.

Advertise in the Farmer

sufficient quantity, others must be overfed and very few in the herd receive the right amount for the best results.

The partially starved cow must have a weakened mammary gland and the decrease in milk flow is accelerated thereby. Not only does this have a detrimental effect upon the cow herself but exerts a marked influence on her progeny. The mammary gland of an overfed cow becomes fat and thus her productiveness is injured as well as that of her offspring. Feeding should then always be individual. That is food should be fed to the cows proportionate to the amount of milk produced. Provided the cows are in good thriving condition the quantity of food given should be such that they neither gain nor lose in flesh.

In large herds it is not an easy matter to feed each cow a different amount according to the quantity of milk given ,but this may be approximated by dividing the herd into groups each individual in a group giving nearly the same amount of milk. It is comparatively easy to group the cows with respect to production and thus with respect to feed. Every herd of any size contains animals which stand practically the same as regards production. These do all right fed the same quantities. But every herd also contains groups of animals vastly different as to production.

There is the 3,000-pound cow, the 5,000 to 6,000-pound cow, the 8,000 and 9,000-pound cow, and the 10,000 to 12,000-pound cow. Grouping the animals according to production for feeding purposes, while not exactly individual feeding, is very near it, if the grouping is properly done, and cannot help bring an improvement on collective feeding. It stands to reason that it takes more feed or energy to produce 12,000 pounds of milk than it does to produce 6,000 pounds and that the cow producing the latter amount required more feed or energy than the one from which only 3,000 pounds of milk is received in a year.

Feeding should also be done with a view to the quality as well as to the quantity of the finished product. Dirty mangers or feeding troughs, musty and strong scented food have a very bad effect upon the milk and butter and too much care cannot be taken to eliminate all such conditions from the feeding of the dairy cows. The success with the herd depends very largely upon the success of each individual going to make up the herd and the success of the individual depends on the feed and care given, such feed and care to be regulated to suit the individual and not a general average for the entire herd. W. H. L.

TO MAINTAIN HIGH STANDARD OF MILK

Milk would never sour but for presence of bacteria and the bacterial content of milk is governed by three factors.

First, is the initial contamination which in substance means carelessness in milking. A dairyman's business depends upon the quality of milk which he sells. A little more care in cleaning the udder and sides of the cow, and using a narrow top milk pail would soon establish a reputation for first-class milk.

Second, the temperature at which milk is kept until delivered to the consumer. A maximum temperature of 50 degrets F. should be insisted upon.

Third, the age of the milk, or the time which elapses between drawing the milk and its consumption. The older the milk the higher the bacterial count. These three factors constitute all that there is in production and delivery of first-class market milk.

Your need of a
DE LAVAL
CREAM SEPARATOR
is greater right now than ever before

These are the days of the full milk pail.

But if you are trying to get along without any cream separator, or with an inferior or half-worn-out machine, the more milk you get the more cream you lose.

And no farmer can afford to lose even a little cream when butter-fat is selling at from 40 to 50 cents a pound.

With butter-fat at present prices, and our country begging us to stop waste, "cream slacker" methods of skimming milk must go.

Get a De Laval right away and put all the cream in the cream can.

There is no other cream separator that can compare with the De Laval in clean skimming, capacity, ease of operation, freedom from repairs and durability.

Order your De Laval now and let it begin saving cream for you right away. Remember that a De Laval may be bought for cash or on such liberal terms as to save its own cost. See the local De Laval agent, or, if you don't know him, write to the nearest De Laval office as below.

STERILITY

Sterility, or impotence, is inability of the animal to reproduce its kind. Such an animal is known as a non-breeder. In the male, impotence is usually due to an absence of the spermatozoa, or male cells. This condition is associated with advancing age or excessive service. In many cases it is due to a peculiar condition of the individual. The best treatment for this condition, which is so often due to debility, is rest and nourishing food, combined with tonic medicines. There is no specific treatment, and all hope of recovery is based on the strengthening and toning up of the whole system.

MILK SECRETION

After an animal has given birth to young, if three is a scant secretion of milk, she should be given plenty of watery food, such as bran mashes and other sloppy food, as these tend to increase the milk flow, and they have a laxative effect on the system. When the udder si swollen or inflamed, soft, watery foods should not be given. The milk may be altered in any one of several particulars. Many times there is little or no fat in the milk. This is caused many times by improper food, such as bad hay or corn stalks. The food should be of the best quality and easy to digest. The animal should be examined as to whether or not any disease interferes with its health.

LIVE STOCK.

MANY GOOD COWS HAVE NEVER BEEN GIVEN A CHANCE

While there are many excellent individual animals and many splendid herds here and there over the length and breadth of our great Dominion, it is well known that the average herd is a long way below what it should be and the worst feature of the whole business is that it is likely to remain so unless many of our farmers and dairymen get a new vision of the possibilities of improvement that are to be found along the highway of energy and application. There are several things that operate against improvement. One of the most formidable of these is Lack of Worthy Ambition. There may be such a thing as being over ambitious, but this rarely happens and when it really does is more often the result of an unworthy objective. Every man should be ambitious along some worthy line; to be anything less is to be practically dormant, unprogressive and even lazy. The dairyman who is satisfied to drag along with a three or four thousand pound per cow herd should get off the highway of progress and out of the way of progressive men so that, not even his influence will be allowed to impede the onward march of those who have got a vision of better things, and who are pushing forward toward the goal of their ambition.

What is the reason that so many men drift along in this state of apparent indifference without putting forth any effort to keep up wtih the procession that is forging ahead toward the goal of success? It is not because as a class they are lazy. Here and there one of a lazy nature may be found, but the majority are hard workers. The fact seems to be that they have got into a rut and the tendency is to think there is no other way so good as the one they are in. Their fathers did things that way and it is good enough for them. What such dairyman need is an educative bomb to throw them out of the rut on to some higher ground, where they can see the other fellow with less hard work and grind forging ahead and making a success of their enterprises.

The second step in the progressive march, is Better Care of the Herd. There are many good cows all over Canada that have never had a square deal; or in other words that have never had a fair chance to demonstrate their ability as producers. It may seem a pretty strong indictment to say that the majority of dairy cows in Canada are not half-fed, but this is literally true. Large numbers of them are milked within eight or ten weeks of calving, if they will give milk that long, and then dried up and fed on straw and hay with very little, if any, roots, meal or ensilage. Again many of them are kept in cold, dark and ill ventilated stables at night with very little bedding between them and a cold dirty floor and then turned out in the barn yard all day in zero weather to shiver around an old straw stack or rub their lice and mange infested skin against a stone wall or the corner of an old rail fence. Then after two or three months of that kind of treatment they are expected to bring into the world a strong healthy calf and be in good condition to go on to grass for a full summer's work at the pail and because they "fail" the owner wonders what "ails them."

What such a farmer needs is a vision of somebody's herd that has been kept in a nice, clean, well lighted, well ventilated, and well whitewashed stable since early fall; that has been fed plenty of good alfalfa or clover hay, corn ensilage, roots and meal with a bunch of good straw to pick over and then to throw under them for a good bed on which to lie night or day, while the snow flies and the mercury goes below the frost line; that has had good wholesome water within reach all the time, where mangers and gutters have been regularly cleaned every day, and the cattle with hair and skin soft and clean from the frequent use of the curry-comb and brush; where flesh, fat and energy has been stored up to support the cows through the trying experience of parturition, to bring forth healthy, vigorous calves, to make large capable udder, and to enter upon the yearly work as dairymaids with all the vim and vigor that is necessary to distinguish themselves in the Record of Performance or any other endurance test.

But of course these men must have the right kind of a cow. How shall they get them? Well, there are two ways. First, if the herd is fairly good, they can pick out the best half, and get rid of the others for beef or in any other possible way, and then select as many good ones as the money will buy. If that does not get all that one can keep and feed well, get some more money. Borrow it if there is no other way, and get a few more; but not to many; use them rairly and give them a chance. Then get a pure-bred bull from a producing family and raise the heifers from the best cows or from all the cows, for all should be good, and as quickly as possible supplant the poorer ones with the best heifers.

The other way is to sell off the old worthless herd for beef as soon as possible, and invest the money in good business cows that under favorable conditions wil not give less than 9,000 pounds of milk in ten months or 300 days. Unless one has pretty good stock on which to grade up this is the quickest and best way, especially if one has the cash with which to secure good stock, and a suitable place to give them proper care. If he can then add to the list a few pure-bred cattle of the right kind, or all of this kind, so much the better, providing he can secure them at reasonable prices, free from disease, from good families on both sides and in good condition. His revenue will then begin almost immediately both in milk products and in registered stock to sell. But success in this line will depend largely upon adaptiability and no man that his not tested his ability out on this line should lauanch heavily in this kind of stock unless he has money to risk, and will not feel the loss if he does not win out.

There are always plenty of cattle of all kinds in the market with which to make a venture either in pure-breds or grades. Many auction salrs of both consignment and dispersion character are always being held. Many animals of very fine breeding and of individual excellence are in these offerings and parties who contemplate improving their herds should attend these sales and look over the stock.

Not only are there females with fine records that will do credit to any herd but there are also bulls with good long family pedigrees behind them which would be a credit to either grade or registered herds. Why not get out of the rut, take one of these home, join the procession and win in the war of good breeding by overcoming the scrub.

MORE MILK & BUTTER
Has no Equal as a Butter and Milk Producer
Milch cows need food rich in nitrogen for two reasons, to rebuild the ordinary waste of tissues and to secure the protein necessary for the milk. This is why nothing can equal "Maple Leaf" Oil Cake as a producer of butter and milk. It increases the flow of the milk and adds to the richness of the cream. Made by the old process and guaranteed absolutely pure. Contains over 35% protein and 33% Carbo Hydrates.
This splendid food is so rich in protein that British Farmers send four thousand miles to secure it.

CARE OF DRY COW LARGELY GOVERNS HER WORK AT PAIL

During the period the cow is dry it it usually the case that she does not receive as good care ond attention ss when she is milking regularly, but this is a great mistake. The cow must have a rest from milk secretion and during this time she should have the best of feed and care, because her system has become run down by the past ten or eleven months' work in the production of milk and butter fat, and the demands made upon her by the calf she is carrying. The better we care for her when dry, the better she will do when she again begins giving milk.

It is the nature of the cow to go dry, and she will usually do it of her own accord. But why is it her nature? Just as it is the nature of a Jersey to conform with the Jersey type and a Holstein to be black and white. It is a characteristic which has been bred into her ever since the beginning of the dairy cow. This does not mean that the men who selected and improved the breeds selected cows which would go dry for a certain period, but they did select cows that would give a large volume of milk per year, and do it for several years. The heavy milk producing cow that is milked right up to calving year after year and not allowed to rest usually becomes worn out in a few years, owing to the great and continuous strain on her constitution.

We have on our farm at the present time some deep milkers that would give milk from one calving to the next if we should continue milking them, but we always allow them a period of rest. We consider six weeks long enough for any cow to go dry. The cow that remains dry for twelve to sixteen weeks is usually a poor one.

The ration for the dry cow should be formulated with three things in mind, namely, to furnish a sufficient amount of protein to develop the fetus properly and allow a surplus for the needs of the body of the cow; to supply enough carbohydrates that the cow may lay on a little fat; and to supply succulence. Some kind of green feed is very essential in the ration for the cow at all times. It serves for the purpose of maintaining the bowels in a loose condition, which is necessary to good digestion and assimilation of food. Corn silage is undoubtedly the best feed to supply succulence although in the absence of this it may be supplied by dried beet pulp or roots. Alfalfa hay, clover hay, cottonseed meal, oil meal and oats are most common among the protein feeds, while the carbohydrates portion of the ration is usually furnished by the corn plant or other similar feeds.

The dry cow must have plenty of good water and on very cold days in winter it is a good plan to warm it just enough to take the chill off. When cows are forced to drink ice-cold water in zero weather they will turn away from it before they have consumed enough to meet their requirements. If salt is sprinkled over the fodder portion of her ration or otherwise supplied at intervals of two or three times a week it will assist in keeping her system in good tone.

The stall in which she is kept should be supplied with good bedding, which when soiled should be removed and a fresh supply added. When the weather will permit the cow should be allowed to remain outside of the barn and not kept confined all the time during the few weeks she is resting from milk secretion. Sunshine, fresh air and exercise are quite necessary to the well-doing of any mother during the period of gestation and the dairy cow is no exception. It is needless to say that the most kind and gentle treatment is very important.—W. H. U.

CLEANLINESS AN EXCELLENT VIRTUE ABOUT A DAIRY BARN

Each year there is bound to be accumulations about the farmyard that will need cleaning up and ridding out in order to keep it in the very best and most sanitary condition. The time for making a thorough clean-up, as I have found it, is just before preparation for spring work begins. Then it is possible to destroy all germ-laden filth that may have accumulated and fill up the low places with good clean soil so there will not be a cesspool at the stable door. For my part I prefer the use of a wheelbarrow in cleaning my stable and have the manure a little

distance from the stable door.

Decayed manure, cesspools and slop are breeding places for flies, and these are the worst germ-carrying agents the farmer has to contend with. Stagnant water is the breeding place of mosquitoes, so I have found it best to fill in all such unnecessary low places about the farm yard witha two-wheel scraper. I use a covered barrel on wheels for the accumulation of garbage at the back door, so that I can remove it to the pigs at regular feeding periods each day. This helps keep the yard clean and does away with a good many flies that bother when an open garbage can is provided.

DIRTY CANS CONTRIBUTE MORE THAN DIRTY BARNS TO MILK CONTAMINATION

Because you can see the dirt which falls into milk at the barn, it has been believed that the barn contributes most of the contamination. But "it is the utensils, rather than the barn, which are largely responsible for the excessive bacterial contamination of milk" says Bulletin No. 204 of the Illinois Experimental Station. For instance, when all the utensils used for handling the milk at the barn were thoroughly steamed, the bottle milk contained only 5,000 bacterial per cubic centimeter, but when the steaming was omitted, the milk frequently contained several hundred thousand bacteria per cubic centimeter. It takes a little more than sixteen cubic centimeters to make a cubic inch.

The cans used for shipping milk, when they are washed at the dairy and returned to the farm without being steamed and dried, usually add many times the number of bacteria to the milk that barn conditions do. The greatest contamination comes from complex apparatus such as botttle fillers. This suggests that the separator, unless it is very carefully washed, is the source of trouble in much of the milk which spoils sooner than it should.

Freshly washed milk cans still harbor large numbers of bacteria. Many persons believe that when they have washed the milk utensils in the ordinary way they have cleaned them of bacteria.

According to the dairy department of the University of Illinois, freshly washed milk cans contain, per can, more than a billion germs; some cans washed at the dairy contained as much as a hundred billion bacteria. But in ordinary practice milk is shipped to the city or to the dairy from the farm. The cans are returned washed and steamed, with the lids on. These cans may stand for two or three days before they are again used.

In order to test the effect of this holding after being washed, the experimenters took 160 eight-gallon cans; 100 of these were steamed, sixty were left unsteamed. The steaming consisted of holding the cans over a jet of steam fifteen pounds of pressure for twenty-five seconds. Cans so steamed are practically bacteria free. Fifty of the steamed and fifty of the unsteamed cans were inverted on a rack with the lids off. The other fifty steamed and ten not steamed were closed immediately after washing. All the cans were then left in a room at a temperature of about 65 degrees for thirty hours.

The cans washed, steamed, uncovered and inverted were dry and fresh, free from bad odors and the number of bacteria was small. The fifty cans washed, steamed and closed were still wet; most of them had a more or less pronounced odor. These cans had a much greater number of bacteria than the unclosed fifty; if the cans had been filled with milk its germ content would have been increased by 1,816 bacteria per cubic centimeter.

The fifty cans not steamed, but uncovered and inverted, were dry, had no particular bad odor, but the number of bacteria found in them was much larger than that found in the steamed cans. It was shown that the destructive effect of drying upon the germ life in the cans was marked, for there were fewer germs left in the cans after drying, when unclosed for thirty hours, than when filled with milk immediately after washing.

The ten cans that were washed, not steamed, and covered and held thirty hours had a decidely bad odor, and contained enormous numbers of bacteria. The conclusion is that if cans are washed, steamed and then left uncovered in a clean place to dry, the best conditions will be had.

In a somewhat similar experiment with bottles, it was shown that when quart milk bottles were washed but not steamed and allowed to stand twenty-four hours, they they contributed twelve times as many bacteria to the milk put into them as did bottles filled immediately after washing.

Similar and extensive trials to discover the relative bacterial contribution of steamed and unsteamed pails, strainers and cans showed that the unsteamed utensils contributed sixty-four times as many bacteria as all other sources of contamination. At another barn the unsteamed cans gave 103 times as many bacteria as the steamed cans showed.

THE DAIRY SIRE THAT IS BRED FOR PRODUCTION

When dairymen say an animal is "bred-for-production" they mean that the animal's ancestors were high milk and butterfat producers. His sire and grandsires, for several generations back, have produced offspring that have made good records in milk and butterfat production; his dam and grandams have been good producers and good breeders as well.

The pedigree should show all these points very plainly. It should also show that some of the ancestors of that particular sire were excellent inhividuals, and were winners in national shows. The better the records and the more near relatives with good records, the better the pedigree.

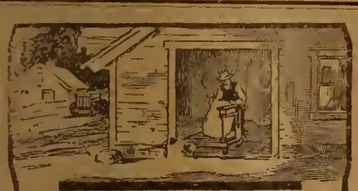
Many an animal has a fine pedigree but is a very poor individual. The right dairy sire should be a good individual, as well as have a good pedigree. He should be fairly typical of his breed, and show capacity, size and quality.

The real value of a dairy sire to any herd is told when his daughters freshen. Then we are able to tell whether or not he is improving the herd. If the daughters are better producers than their dams were at the same age, we are on the right track. A sire which does not improve the herd, and whose daughters are not better than their dams, should be sold at once. The sire which does not improve a herd should either be kept in the herd or sold to someone who can use him as a breeder. . aMny good sires have been sold to butchers before their real value became known.

The dairy sire should be grown well from the day of his birth and not be allowed to become stunted—size is one of the important qualities in a dairy sire. In winter, silage or roots should be fed but only in small quantities. A growing bull sometimes should not receive more than five pounds of silage a day, and when full-grown not more than 10 to 15 pounds. Too much silage may cause him to become an uncertain breeder. A good ration is—silage 8 to 15 pounds, hay 10 to 12 pounds and from 2 to 4 pounds of a grain mixture consisting of three parts of oats and one of bran.

To be healthy and good tempered a dairy bull must have plenty of exercise. A roomy, well-fenced paddock where he can exercise at will, will pay for itself in good results. A heavy block hung in the centre of the paddock that he may play with makes a good exerciser. Have the stall clean, light, and well ventilated and have it large enough so that he may have his head free when lying down.

A bull sould be handled from the time he is six months old. If handled when he is young he will give less trouble when he is older. Put a ring in his nose when he is a year old and always use a staff in handling him. Never trust a dairy bull. He is a bull and ilable to do damage at any time if givena chance. Always let the bull understand that you are his master—but be kind as well os firm.



Handy Scales for Farm Use

Convenience and service are the chief features of the

Fairbanks Farm Scales

The handle at the base of the weighing post permits of ready transportation on its own wheels to any part of the farm buildings. In house or barn or dairy it serves any purpose up to 2000 pounds capacity.

Fairbanks Portable Farm Scales are compact and absolutely accurate. The platform is 34 x 25½ inches and has a clearance of 11 3-8 inches above the ground.

Write our nearest branch for full details of this and other types of scales.

The Canadian Fairbanks-Morse Co., Limited

Fairbanks Scales are the World's Standard for accurate weighing.

You've no time to waste

IF you expect to get your silo erected in time to take care of your 1918 corn crop, don't put off placing your order a day longer.

With the railroads congested with war traffic, no manufacturer can guarantee prompt deliveries very far ahead.

Be forehanded. Allow for freight delays and uncertainties. Give yourself time to erect your silo properly.

Plan to Install an IDEAL GREEN FEED SILO Right Away

The Ideal is the most economical silo you can buy, because it not only produces the best silage but will pay its own cost the first year and will last from 20 to 30 years.

Just ask any Ideal user how he likes his silo. He'll tell you that you can make no mistake in buying an Ideal—that the sooner you get it on your farm, the better off you'll be.

Write today for our illustrated catalogue.

THE HORSE

SKILL REQUIRED TO GIVE CARE TO GRASS FED AND PARTIALLY IDLE HORSES

There is no better way to get acquainted with the horse's needs in his domesticated life than by fully realizing the qualities and desires he has inherited from his wild progenitors. Whatever condition the farmer places him under in using him as a factor of economy and utility on the farm, he must fulfil, in as far as he is able, all that nature demands in his treatment.

Meantime, after the strenuous work of spring has abated somewhat, there is the short period of time when the horse gets a little experience of the open and free life of the field he is so fitted by nature to enjoy. In the prairie life his progenitors had the advantage of a choice of pasturage over areas extending to thousands of square miles. Their fleetness of limb enabled them to scour the country and follow tender vegettoon as it grew. The very fire and spirit which breeders wish to cultivate in the domestic horse comes from the life as it was generated on the prairie. It is the lingering innature of feeding. Many of these conditions can be imitated at this season while the domesticated horse is enjoying the free life on the prairie.

On not a few farms that have come under the observation of the writer the horse that ought to be enjoying respite from the heavy labor of spring is subjected to another form of slavery by being enclosed in a fenced field of weeds and worn out pasture. In treatment like this there is no chance for the horse to regain the lost energy and flesh through hard work at tillage and seeding.

From the general appearance of the average horse on the farm as spring approaches, he badly requires the best summer conditions to bring lustre and life to his ill-fed condition of winter. Too often he arrives at the springtide in bad shape for work, and generally would require all the summer to recuperate without the intermediate period of work between winter and summer. Few farmers know or realize the fact that horses that have long spells of idleness and long spells of work require more skilled attention and thought than the horse that is in harness all the time.

Where the Horse Thrives Best

If a horse has to do the spring work after a winter of half starvation or careless attention, and then gets the poorest pasture in the summer as his reward, what hope is there for the breeding of the best class of horses, a work so necessary to the welfare of the country and to the interest of the individual farmer.

The horse does not require luxurient pasture, he loves and thrives best on the young growing colver and mixed pastures of good quality. A pasture of this quality that is just recovering from being eaten down by cattle or sheep is best adapted for the horse. It is a fact that this has been noted in seep raising countries that the horse seems to favor the pasture that has been eaten down sheep.

The portions of the fields that are in the best state of cultivation is generally found to be the place where the horse grazes. Low lying, weedy and wet pastures are not relished by horses, and if forced to feed on these they become a serious source of danger to the health of the animal. It is in the farmer's own interest, and, to say the least, it is only humane to look out the nicest spots of pasure for the faithful horse. It will repay ten fold in motive power on the farm and in money profit, for feeding and attention to the likes and dislikes of the horse is a valuable supplement to good breeding. Careless attention to this detail in horse attention will destroy the good work of high class breeding. This observation has been made previously in these articles, but it is a truth of so vital importance to live stock breeding that it cannot be too often kept before farm readers.

Working the Horse on Grass Ration

When extra work or a hurried jog is required of the horse during the time he is on pasture, the system of doing it is often injudicious. He is generally taken from the field after he has been in it a few days or weeks and is hurriedly hitched up and started at some arduous duty. It would be far better to take the horse in the previous evening, or at least a few hours before his work is started.

Another precaution to take in summer time is the watering of the horse. Always give the horse soft water to drink, and not too cold. Instinct or experience has made the horse conscious of this, for he will never drink hard or cold water if he has access to soft water; he will leave the most transpareit anr pure water of the well for a river, although the water may be of the mudiest quality. Hard, cold water acts on the sensitive coat of the stomach injuriously, often giving gripes or colic.

Another custom that some horses are subjected to is that of bolting hurriedly a feed of whole oats when they are taken from the pasture and before they are hitched up. This is usually done to horses that are said to "hard to keep." Some animals are said to be more "easily kept" than others. This usually depends on the greater perfecttion of their digestive organs. They assimilate all the nutriment there is in their food, while a horse that is "hard to keep" will generally be found to pass with his excrements a considerable percentage of undigested aliment. In a case where a horse belongs to the class that is termed "hard to keep," it is better to give him grain feed in a ground condition, and when his stomach is empty and not full of grass. The dgestive fluids will act on it more easily, allowing at the same time a moderate quantity of water. A horse of this variety will be benefited by a mild tonic as he is put to grass.

It must always be remembered the horse has but one stomach, and it is a small one for his size. When he is subjected to lengthened hours of labor he gets very hungry. In feeding in the winter time this can be regulated, but in the summer time when the horse can take his fill of grass he is apt to take too much if let out to grass hot and tired. He should be kept in the stable till cool, and should be groomed and fed some oats or hay before he is let out to pasture.

The care of the farm horse at alll times is one that demands some skill and much of the mortality and disease found among horses is due to a lack of attention or study of the conditions that fit the horse organism.—O. V. J.

FIT HARNESS TO HORSE AND GAIN BEST RESULTS FROM HIS PULLING POWER

Bad fitting harness is a great waster of feed and horse power. The high spirit and muscular activity accomplished by intelligent management in breeding and feeding, gets a rude check when hitched to the farm implement with hard and illfitting harness. However, faithful and willing the animal is to generate his maximum amount of power, he cannot be expected to accomplish his alloted work if undergoing pain. From a humanitarian point of view, it is a crime, as well as a short-sighted farm policy. Pain in the horse brings its own punishment to the farmer. It is a loss to production, that no available manual labor can supplement. There is evidence on every hand among horses on the farm field and city street of the positive bad usage that thew are subjected to by ill-fitting equipment. There is more cruelay and loss in this department of the idustry than the average farmer is aware of. The dumb animal speaks forcibly of the crime perpetrated against its own and its owner's best interests, by changed conformation and lack of spirit in the work.

All the injuries to horses, such as poll evil, fistulous withers, shoulder sores, are mostly caused by ill-fitting harness, and van easily be avoided. Poorly fitting collars and neglect of their parts themselves are potent causes of shoulder and neck troubles. They are a common source of pain to the horse, and sheer carlessness on the part of the teamster is the only cause. For efficiency in pulling power the teamster must fit the collar to the horse, and not the horse to the collar, which we see so often attempted.

At the noon-day hour all the harness should be taken off. It is sheer nonsense for the teamster or farmer to say there is no time left him at midday to look after the harness or the horses' soulders. A ten minutes chore at mid-day will conserve many times over the ability of the horse in the field. It is more necessary than any ither work in connection with teaming that the harness be removed and the padding of collar cleaned, dried and aired in the sunshine. The skin below the harness gets cooled off, and opportunity is given to clean and brush the parts.

The spring time finds the horse shedding its coat of hair, and this makes it all the more necessary to exercise more care in keeping him clean with brush and comb. Old hair, dandruff, dust and sweat make up a combination that irritates the tender skin in the process of removal and the badly fitting collar completes the job of spoiling the shoulder and lessening the pulling power.

The necks and soulders of horses are found to differ about as much in shape as those of people, so a collar fitting one horse is oftentimes a misfit for another.

Every horse should have its own collar, in fact, all the harness sould be fitted to each animal. The throwing on of any harness that comes first to hand on any team that is chosen to be hitched up is aonther source of waste om horse power. How fould the teamster feed if the same treatment were meted out to him in the matter of his daily attire, or working equipment? Blistered feet would only be one of the results; it's more than probable that total incapacity would be the finishing touch.

The care of these important parts of the horse's body is simple enough if the proper care is taken in fitting the harness. In hot summer weather it is good practice to wash the shoulders and necks of horses every evening

GOMBAULT'S
CAUSTIC BALSAM

A safe, speedy and positive cure for

Curb, Splint, Sweeny, Capped Hock, Strained Tendons, Founder, Wind Puffs, and all lameness from Spavin, Ringbone and other bony tumors. Cures all skin diseases or Parasites, Thrush, Diphtheria. Removes all Bunches from Horses or Cattle.

when the collar is removed. It sould never be done just before the animal is to be worked. for the skin should always be dry whei the colar is to work upon it. Cold salt water. water with a little vinegar added, or about one per cent, alum water, are good washes that will toughen the skin. If the skin is broken, salt water should not be used.

As the season progresses it will be necessary to readjust the harness as the horses get thinner.

Shoulder sweeny. and abcesses are formed when the collar is too wide and stands away from the side of the neck. The best way to know the right length of collar is to hold the animal's head at the natural position when pulling andinsert the hand between the collar and the breast or throat. If there is just room for the open hand to slip in between. then the collar will be the correct length. A collar too long will bruise the shoulder points and o collar to short is apt to choke the animal and will blister the whole surface on which it presses.

Tight girthing is never necessary, and the breeching should hang in the right place and be just tight enough to come into play when the tugs are slack.

Teh cultivating implements must also be kept in good working shape, if the full utility of the horse is desired. It has been found on trial that a blunt share reuqires a third more pulling power from the team than a sharp one. Besides sharp shares, sharp reaper blades and well oiled machinery reduces the cost of horses' power, and the groans from the wagon wheel for lack of grease comes as a curse on the industry, as it is carried on by the indifferent teamster.

BOT FLIES THAT TORMENT THE HORSES

Along about this time of the year, the horses are bothered a lot by the bot flies. These flies strike the animals under the chin and on the forelegs, and every strike means the deposit of an egg or "nit." Whether or not the flies actually cause the animals pain is no known but they are greatly annoyed, as is the man who is working them. It is probble that the peculiar buzzing noise made by the flies is what the horses dislike. but whatever it is, the nits they leave may become the source of trouble. These nits are licked off by the horse and hatch into bots that cause indigestion and stomach disorders. When grooming the horse the nits shoull be scraped off with a sharp knife or they may be destroyed by rubbing the animal with a rag wet with kerosene.

LEATHER WASHERS THAT ARE PLIABLE

The farmer who carries in stock a supply of leather washers for use on. pumps o rother machinery often finds the oil dried out of the leather and the washers hardened so as to be useless. Deterioration is always rapid if the washers are stored without protection.

A method of keeping them that has been found satisfactory is to pack the leather washers in a tin or galvanized iron box and cover them with melted tallow. It has been found that since these parts are made from an animal substance, the covering or grease used should also be of an animal origin. On removal from the pack these washers are sufficiently pliable for use.

THE FOAL

It is known to all experienced breeders of horses that much of the success of raising colts depends upon the care given the mare during pregnancy and at the time of parturition. The feeding and general care as to exercise and treatment are important factors in the rearing of good colts. Mares should have exercise in some form during pregnancy, either in the way of work, which should not be too laborious, or by allowing them to run out at grass, where exercise is had by constantly moving. But light work is the most healthful kind of exercise for mares, for the reason that they can be fed much more nutritious food by having work of this kind. Physic should be given the foal when artificialfood is fed, either castor oil or olive oil, to relieve the constipation that nearly always occurs. Colts are usually weaned at from five to six months old. Calves are usually taken from the cows two or three days after calving, as soon as the milk becomes normal. Pigs are weaned at about two months old, and lambs at three to four months. After weaning, the udder of the dam should be milked often enough to relieve the pressure and to prevent inflammation. When it is desired to "dry off" the dam, the udder should not be milked dry.

Pyemia, or blood-poisoning, in young colts is a disease due to infection by pus-producing bacteria. The disease usually occurs within two or three weeks after the colt is foaled. The early stages of the disease, pus collects in the pockets or swellings, and the joints are swollen in the affected region, with stiffness and difficult locomotion. If the pockets are not opened, the pus often burrows along the tendens and about the joints, and finally breaks and discharges as a thin yellow fluid from pockets that spread in various directions. The infection arises from a wound of some kind. In many cases the navel is the seat of infection. When this disease is neglected, the colt becomes dull, loses appetite, lies in the sun and grows weak. Death results when the animal is not properly cared for. All pockets containing pus should be opened freely and washed out with warm water, and a solution of corrosive sublimate 1-1000 Sol.) should be used. Or a solution of hydrogen peroxide may be used in washing the pus pockets after they have been cleansed with warm water. An infected navel should be treated with peroxide of hydrogen, or tincture of iodine, or Lysel.

TO BREED MILITARY REMOUNTS

The Mance Farming Co., Ltd., Mance, near Viking, Alta., purchased recently at Montreal, Que., a new thoroughbred stallion, for their stud, "Vance Guard", sired by the famous long distance champion, "Advance Guard." This horse is of splendid proportions and of exceptional size and substance. He has stood champion of the breed in Ontario and Manitoba.

The company, which is under the management of Joseph Lambert, the well known horseman of Edmonton, is going into the breeding of military remounts and the new sire should work in well for this purpose.

POULTRY.

CRATE FEEDING

What is it? It is enclosing birds in small coops or crates for the last few weeks' fininshing before killing for the market.

What advantage has this method? It keeps the birds quiet and under control. No flesh is wasted or muscles hardened by undue exercise. The added flesh during this finishing process is the cheapest of the whole bird to produce, and it increases the value of the whole carcass from 10 to 25 per cent.

How is the crate made? Almost any packing box wil answer for a temporary crate, but is better to make a good one that will last. The crates in general use are six feet long by sixteen inches wide by twenty inches high and divided into thre ecompartments. They are made of laths or slats nailed on a light frame.

What kind of a bird? The flesh of any bird is improved by finishing in the crate. Best results are obtained from cockerels of the general purpose and heavy breeds.

What is the best feed? Finely ground grains mixed with milk make the best ration. Oats, barley, corn, and buckwheat are all good. Two or three grains mixed together are better than one alone. Wild buckwheat screenings also make a cheap and satisfactory feed. Milk, preferably sour, or buttermilk, is very valuable for mixing feed.

Other things to remember.—Do not feed the birds for twenty-four hours after putting them in the crate, and then feed very sparingly for several days. Keep the birds hungry for two or three days and gradually increase until a full feed is given; then feed twice a day just what they will eat up clean. Clean out any feed left in the trough after each meal. Dust the birds for lice before starting, and again before killing. Kill by bleeding in the mouth and piercing the brain. Pluck, dry and cool before packing. Write Experimental Farm for Bulletin No. 88 for further information.—F. C. Elford, Dominion Poultry Husbandman.

REARING CHICKS

Taking chicks from the brooder.—When the chicks are sufficiently large that they spend most of their time outside the hover and the risk of cold nights is pretty well over, the heat may be removed from the broodes or colony houses and the chicks given the whole house. If there is any fear of chilling it is better to leave some heat even after it is thought unnecessary rather than to run the risk of chilling and overcrowding.

Rearing Coops.—If the brooder has been placed in a coop large neough to accommodate the partially grown chicks they can remain in the coop after the brooder is taken out. If the brooder is in a colony house this will make an ideal rearing coop for chicks, at least until they have grown to a considerable size when additional accommodation may have to be provided.

No matter what the coop is, see that it is kept clean and sanitary. Give plenty of ventilation without draughts. A flat roost or two will soon train the chicks to perch and will help prevent them crowding in case of cold nights.

Feeding.—It is not well to change the character of the feed too suddenly. If the change from chick feeds to cheaper feeds has not already been made in the brooding coop make a change gradually. If there is plenty of range the hopper feeding system may be largely introduced. Cracked or small grains may be placed in one hopper and a dry mash consisting of ground grains or a mixture of these with bran and shorts, placed in another hopper.

This year as last the basis of our feed for the growing chicks will be buckwheat screenings. These will be fed principally ground. in a hopper.

A better growth will be obtained if moistened mash is given to the chicks once a day. The same mixture as is used in the dry mash hopper may be utilized for this.

Milk of some kind is very valuable to the growing chicks whether it be buttermilk or skim milk. It can be given them to drink and used to moisten the mash.

If the moist mash causes too much labor the chicks will thrive well on the dry hopper feeds but see that they have plenty. It never pays to stint the growing hicks.

Range.—If possible give the growing chicks fresh range. This can be done by placing the colony house or coop in the orchard, in the pasture field, the corn field, the root field or any place where there is some green feed and shade. Shade is important especially during the hot season. If the chicks are being raised in smaller quarters or in back yards it is a good plan to alternate their yards, sowing something green from time to time. A few sunflowers or artichokes will provide shade and rye, rape or other green crops makes a satisfactor green feed.

Selling the Cockerels.—It is not always wise to wait until fall before the cockerels are selected and eaten or sold. Especially is this the case if the range is limited. Watch the markets. If prices are good for broilers kill off the cockerels as they are ready. Very often a two pound chick will bring as much as the same chick three months later when it weighs five pounds.

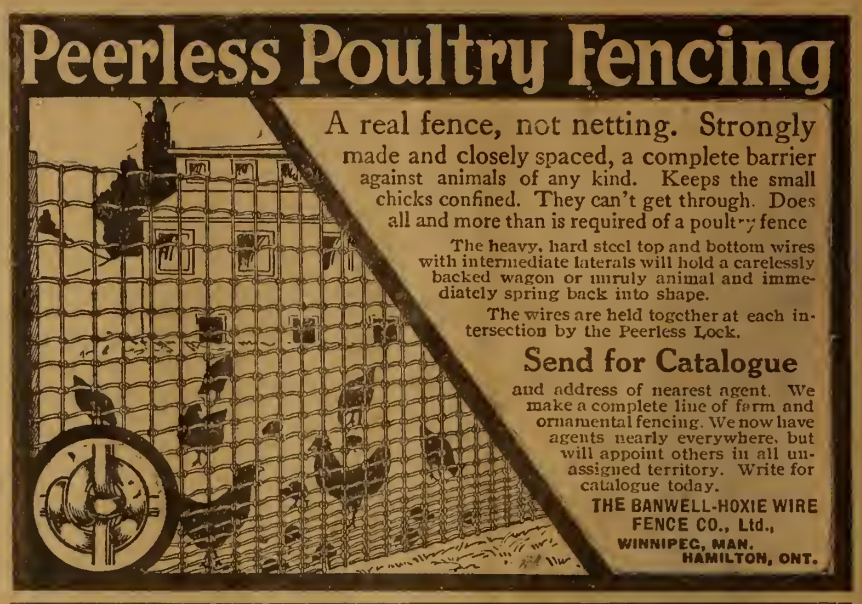
The early Pullets.—If the chicks are early and some of the pullets are showing signs of maturity it will be well to separate them from the rest of the flock. Give them special care and before they begin to lay put them into their winter houses. Too much care cannot be given the pullets at this time. They mean early winter eggs late this fall and next winter when the prices are the highest.

FEEDING MILK IN THE POULTRY YARD

Everybody who has given the matter attention has learned that laying hens to do their best and young growing fowls need animal food in addition to grain and roughage. There is no other way of balancing the ration. Pullets grown without animal food do not mature nor begin to lay as early as those provided with it, but on the farm beef scrap is too expensive. The feeding of meat would be a great handicap to poultry raisers if it were not for the fact that there is usually a plentiful supply of skimmed milk on the farm. This is a great advantage for experiments in all the agricultural departments of the various countries interested in poultry culture have shown that milk not only takes the place of meat but gives better results.

The overfeeding of meat or the use of meat not properly selected, while increasing the egg yield, lowers the fertility and the vitality of the eggs. Pullets raised on as much meat as is necessary for the fastest possible growth, do not make a good breeders as those raised on milk. For finishing off the cockerels thatare to be sold for broilers nothing beats a mash mixed with milk instead of water.

The best of poultry foods (milk) is greatly neglected because its value and right methods of feeding it are not understood. One day last summer I was saying to a farmer what I have just written. "You read that in a puoltry journal didn't you?" he said. "I read it too, and wish I hadn't. I put skimmed milk directly from the separator in the chicks' drinking vessel and put a panful out for the hens. It killed a lot of the chicks and made some of the hens sick, even some of the grown hens died. I don't think I'll follow any more of the advice printed in the papers about feeding poultry. Anyhow I'll feed no more milk."



Peerless Poultry Fencing
A real fence, not netting. Strongly made and closely spaced, a complete barrier against animals of any kind. Keeps the small chicks confined. They can't get through. Does all and more than is required of a poultry fence
The heavy, hard steel top and bottom wires with intermediate laterals will hold a carelessly backed wagon or unruly animal and immediately spring back into shape.
The wires are held together at each intersection by the Peerless Lock.
Send for Catalogue
and address of nearest agent. We make a complete line of farm and ornamental fencing. We now have agents nearly everywhere, but will appoint others in all unassigned territory. Write for catalogue today.
THE BANWELL-HOXIE WIRE FENCE CO., Ltd.,
WINNIPEG, MAN.
HAMILTON, ONT.

There is no other domestic animal so susceptible to change of diet as a fowl. Even a change of grain will sometimes kill young chicks if they are given all they will eat before they become accustomed to the change and it will often cause hens to stop laying though not likely to kill them. Too much food of any kind will kill young chicks. Next to vermin, overfeeding is the chief cause of loss of chicks on the farm.

The above mentioned farmer gave his hens and chicks all the fresh sweet skimmed milk they could drink at the first feeding of milk, whereas he should have let it sour and then give them a little to start with and increased it gradually till they were sufficiently accustomed to it to drink all they wanted without injury.

One of the chief difficulties in poultry raising is the fact that there are so many little details in it, the neglect of which will mean disaster. There is little real difficulty in it but needs an interested close observer to see all the little things that count. The farmer I mention has his pullets growing more slowly than they should, laying later than necessary and his hens laying less than their best, because he failed to learn one must be cautious about a change of feed in fowls, especially when the change concerns something of which they are so fond that they are likely to overdo the matter.

There is no harm that can come to poultry from feeding sour milk properly. There are scientists who think they have proved that the bacteria which cause milk to sour destroy the germs of bowel diseases both in fowls and in men. Be that as it may, one is missing an opportunity who neglects to feed milk properly to his fowls.—W. H.

TURKEYS NOT HARD TO REAR ONCE YOU KNOW THE WAY

To be successful with turkeys one must understand something about their habits as well as their requirements. One must have a liking for the work and attend to their wants cheerfully. If the breeder has an interest in his flock, he can be assured of success. For many years I have raised flocks ranging from 15 to 50, but last year was my banner year. I have tried several varieties, but have decided to stick to the Bronze. This variety is possessed of strong vitality, they grow extremely large, are good foragers, and withstand the hard winters better than some ofher varieties. My only complaint of them is that they range at such distance that if they are not brought home at night they soon become wild and timid. But after they are half grown they can be practically take care of themeslves if allowed to run. This cannot be said of some other varieties I have raised.

My method is to allow the turkey hen to hatch out the poults and raise them. I have raised poults with chicken hens rather successfully, but one thing I have noticed in particular is that the chicken hen does not know the requirements of the little trukeys

The Little Wonder Cycle Hatcher

Hatches every Hatchable Egg, holds 50 eggs, made entirely of metal, except insulation; self regulating; requires no supplied moisture and will last a life-time. Shipping weight 20 lbs.

(Patented)

Price $10.00

Boxed and delivered to any railway station in the Maritime Provinces.

We manufacture all sizes of Incubators, Brooders, Coal Burning Brooders, and a full line of Supplies.

Model Incubator Co., Limited,

192 River Street, Toronto, Ont.

HAULING BIGGER LOADS

without extra spanning is easily accomplished when you use

MICA AXLE GREASE

"Use half as much as any other"

Axles are rough and porous, causing friction. The mica flakes fill the pores and the grease keeps them there. Mica Grease prevents locked wheels and hot boxes, gives sure relief for unnecessary strain on horses and harness.

EUREKA HARNESS OIL

"Lengthens leather life"

replaces the natural oils that dry out of the leather and puts new life in old harness. It penetrates the leather leaving it soft and pliable, and overcomes the worst enemies of harness—water and dirt.

Sold in standard sized packages by live dealers everywhere.

IMPERIAL OIL LIMITED

BRANCHES IN ALL CITIES

nearly so well as a turkey mother does and the little fellows have a much harder time ge tting started properly. They may be healthy but somehow they do not seem to grow as fast as those that are reared with a turkey hen.

One of the very best feeds for young turkeys is corn bread crumbled. The bread should be allowed to become hard and somewhat stale when it will prove excellent for feeding. Lettuce leaves and clover make up the green feed they require, but they must be fed in small quantities at first. We keep our poults in dry pens for a week and even longer sometimes, until they have plenty of life and seem strong enough to follow the hen without any trouble. On wet days they are penned up, and are never left out during the wet mornings when the grass is covered with dew. When poults are a month old they may be let run and the care that was so essential at first becomes less important as they grow older. However, during storms of wind and rain, I always make it a rule to get the poults shut up if we are able to get them. Sometimes they wander so far this cannot be done, and then the losses come, as we find some of them drowned. This often occurs when they are a fair size.

Turkeys should be fed lightly at morning, noon and night, but as they get older they will not come home for their noonday meal. However, they will be on hand at night if fed regularly. It always makes a breeder feel good to see the turkeys come home at night looking so well and strong.

There is a way of observing the difference in rearing poultry with turkey hens and with chicken hens. This is to raise some one way and some the other, noting carefully the difference in growth. Give the same feed and chance and you will find that the ones that stay around the house with the chicken hen do not grow lige the ones that wander with the turkey mother. Every breeder should make this experiment if he wishes to derive a profit from turkey raising.—Mrs. E. O. S.

BREEDING FOR EGG PRODUCTION

This is a time when more attnetion must be given to efficient work and economical production. This comes home to the farmer and poultryman, for the time has come when the cost of feeding is such an important factor that no man can afford to keep a cow or even a hen that is noe a profitable producer. For this reason we have got to give more attention to breeding and selection; if we do not, the profit from our good individuals will be eaten up by our low producers.

The breeding for egg production is not half as complicated a process as many believe. . To be sure, with the trapnest method it was, but in these times of scarce and high priced labor, one cannot afford to chase traps. It is the persistent layer that we want to find. Most any hen will lay through April, May and June, but the hen that commences at maturity and continues for 10 months is a good hen. If she lays without molting for 12 months, she is an extra good one, but if when moulting time comes she cannot spare the time, but continues on, perhaps will go into January, before moulting, that is the cracker-jack hen, the top-notcher upon which you want to put on at least two blue leg bands and keep her and mate her with the best shaped and most vigorous cockerel you have to raise your breeding cockerels for another year. It has been proven beyond a reasonable doubt that egg production is inherited from the hen through her sons. Thus the importance of finding this "high hen" to get breeding males from. To locate her is not so hard a task as might appear. It is simply a process of elimination.

Go through your flock the first of August and pick out all the hens that have commenced to moult. These are all slackers that have been waiting for an excuse to stop laying. Ship them to market, and the next day you will get just as many eggs and you will have materially reduced your feed bill. Do this same thing Sept. 1 and again Oct. 1. After that, keep all hens that were laying at that date but continue to cull until you have found the hen that has kept on her job the longest. This last hen is your way to success as far as breeding profitable layers is concerned, if you mate her to a good shaped and vigorous male and ues the cockerel from that mating to head your breeding pens.—H. M. Tucker, Chief, Bureau Animal Industry.

ENORMOUS ANNUAL LOSS IN EGG CROP

The conditions under which eggs are produced on many farms should be greatly improved; such improvement will result in a higher average annual price to producers, a higher grade product for the consumers and the elimination to a great extent of the present enormous annual wasteage of the egg crop. Very often the fowls are fed on unwholesome food, which affects the odor and flavor of the eggs. Meat spots, blood spots and bloody eggs cannot be avoided but they should not be sold with the rest of the eggs. Blood rings and rotten eggs are caused by having the males with the females during warm weather or when broody hens sit upon the eggs. Musty and mouldy eggs result from storing the eggs in bad places. Hair-splits, checks and leakers are caused by rough handling either at home or after the eggs have been sold.

Producers are strongly advised to keep the hens in comfortable, sanitary houses and give them clean nests at all times. Eggs should be gathered regularly twict daily in warm weather and once at other times of the year. The eggs should be stored in a cool, dry room at a temperature not higher than 60 degress F., and every precaution should be taken to keep the eggs out of the sunlight as much as possible. All mature male birds should be killed or sold as soon as the breeding season is over, and they should be kept out of the laying flock, except during the breeding season.—M. A. Jull, Macdonald College.

PALMER'S Summer Packs for the S.O.S.

The "Soldiers of the Soil" recruits need Palmer's Summer Packs, or plough Shoes as they are often called, to keep their feet in good condition while doing hard farm work which their feet are not accustomed to.

Even farmers whose feet are hardened to farm labor find Palmer's Summer Packs very restful to tired, aching, burning feet. They are light in weight, roomy, pliable, comfortable, durable and waterproof.

Get a pair from your dealer. Look for the "Moose Head Brand"—stamped on every pair—a warranty of satisfaction.

JOHN PALMER COMPANY, LIMITED
Fredericton, N.B., Canada 86

HANDLING BROODY HENS

The three principal means to adopt in breaking up broody hens are: Air circulating under the hen, plenty of water and feed for them to work on when they are restless, and the society of the flock. Use a coop with a bottom made of narrow slats or of laths, preferably on edge, and set this coop where the other hens work all around it, and have a water fountain and self feeder attached to the side. Seldom will one have to keep the hens in this coop for more than three days.

Breaking up quickly is important, for a hen is a laying machine, and it is necessary for her to keep up her vigor and condition to be laying at her best. To leave the hens on the nests a week or so they become poor and have the setting fever so well established they are much harder to stop, and it takes them longer to get back to egg laying. If the hens are taken off as soon as they stay on the nest over night it will be easy to induce them to stop, and then they go to laying again with almost no interval between. At the price of poultry feeds now it behooves us to have no unproductive intervals.

TO GET RID OF MITES

Clean out the house and thoroughly sweep, not forgetting the windows, walls and ceiling. When this is all swept out clean, use a garden hose or a stiff brush and hot water. See that everything in the cracks and crevices is washed out. After this is done allow the house to dry for a while, and if everything then appears to be clean, use a good disinfectant, and be sure that the solution is forced by the spray or brush right into the cracks and crevices.

If the mites are bad, use boiling hot water followed by coal oil and a liquid lice killer or lice paint. Be sure that this goes into the cracks and crevices and when you have gone over your house thoroughly according to the above treatment, in all probability the mites will be exterminated, but it is advisable in the course of three or four days again to inspect for the mites, and perhaps to repeat the dose once more.—E. F. N.

CONSERVING AND PRESERVING EGGS

The Poultry Department of the Agricultural College issued a bulletin on the above subject which contains information of value to every householder in the Province. The different methods of preserving eggs and how to prepare the solutions ode freely explained in this bulletin. Persons requiring information on this subject should make application for this bulletin at once.

ACADIA UNIVERSITY
WOLFVILLE - - Nova Scotia.

Departments
Arts and Sciences. Applied Science. Theology.

Degrees
B.A., B.Sc., B.Th., M.A., and certificates admitting to the best technical schools. First two years in Agriculture given as electives in B.Sc. course. First year in Medicine, Law, and Theology given as electives in B.A. course.

Special Courses
Courses in Surveying, Draughting, Shopwork, Chemistry, Electricity, and Bacteriology, for returned soldiers and men anticipating military service.

Equipment
Largest undergraduate faculty in the Maritime Provinces. Three new and splendidly equipped Science Buildings.

Expenses
Expenses light, and over $1,000.00 given in prizes and scholarships yearly. Send for calendar to

Rev. GEORGE B. CUTTEN, Ph.D., D.D., LL.D., President.
Next term begins Oct. 2nd, 1918.

ACADIA LADIES' SEMINARY
WOLFVILLE - - Nova Scotia.

The Aim. — To prepare Girls and Young Women for Complete Living.
The Courses.—Twelve; including College Matriculation, General, Music, Art, Expression, Household Science, Business.

Next term opens Sept. 4th, 1918.

FOR HOME AND COUNTRY

This Department will be utilized to the best interests of the homes in the Maritime Provinces. Subjects relating to household science and all that stands for better homes and communities will be published on this page. The editor, Mrs. M. A. MacLeod, Sussex, N. B., solicits your assistance in making this page a success and will be glad to publish tested recipes, household discoveries and other articles useful to the homemaker and women's or-ganizations.

THE OTHER WIFE

(By Katharine Reynolds)

They had met suddenly in the fog in a little blind pocket of London. Jack Peyton was hurrying to catch a train which would meet a certain boat and he had only a minute. So he stopped, smiled, shook hands and said, "Hello, Mollie! What in thunder are you doing here? Jerry's in town—and the new bride—staying at the Cecil. I'm off to Constantiunople—have to make the next boat—say hello for me to everybody—good-by."

He was gone and Mollie walked on and through the gray gloom, with, "Jerry's in town—and the new bride" beating an endless merry chorus on her naked fog-soaked brain. And after a long gray while she found herself one gray atom in a long line of gray atoms that crawled through gray gloom into a ghostly gray ship.

The line of gray atoms dwindled, melted up the gray ship's side and soon after the boat moved. Mollie stood beside the rail and stared out into the fiendish fog, while the singing little devils sitting in thick rows on the top of her head kicked up their fiendish heels and beat their anvils and shrieked, "He's staying at the Cecil."

She decided to go to her stateroom. Maybe if she buried her head in the pillows she could smother the singing imps into silence.

She turned from the rail. It was over—the terrible danger of meeting.

As she passed from the muddy gloom into the brilliant light of the passageway, her eyes were blinded. She stumbled on the first landing and a man caught her. She looked up to smile her conventional thanks and smiled right up into Jerry's gray eyes.

"Why—Mollie, girl—" He paused and a change came over his face.

She was suddenly calm.

"I'm stumbling down to my stateroom Jerry, with one of my old headaches. It's just this etnernal fog and dead grayness."

"I'm sorry," he spoke more easily now. "Have the stewardess fill your hot water bag for the back of your neck and lie still and don't worry—about anything." He added the last two words slowly and she thought she understood.

As she went on she told herself that she had always known that if they ever met again, Jerry would be just like that—comfortable and friendly and sincere.

It didn't seem possible that they were no longer man and wife. That somewhere on this same boat was a girl who was Jerry's new bride. The whole thing was a preposterous, silly nightmare, a gray myth that would melt with the fog. It couldn't be—it couldn't——

But he had told her not to worry—about anything. How often he had told her that very same thing in the old days back there in the old white house. And she had never heeded him—used to fly into a rage of despair because he didn't seem ambitious enough. At the bitter end she had told herself that he had no brains, no ideals, no plans; just that maddening content, that childish faith that all things would come to them if they just lived sanely and contentedly from day to day and waited. But she had not cared to wait.

So she left the little hills and bits of woodland, the old white house, serene and wise with years; left old true friends and flower faces and went to new York where life boils at white heat and where—so simple souls believe—the feast is ever ready and every stray stranger is eagerly sought out and welcomed.

It was then that she found out her mistake. In those first three months she learned all and more than ever Jerry had tried to teach her.

She wanted to go back then. But the cruel pride that holds young hearts in bondage would not let her. And then, one day, se found out that it was too late; that Jerry was no longer in white house; that he had passed through the hot city and sailed away in a huge ship, out of the harbor, away from her and home shores.

He had passed through and she had not known—nothing had told her.

So then there was nothing but work to still the donging, fiill the hours and days and months—nothing else that could make her heart forget hunger.

Then one day when even great success left her homesick heart cold, she said to herself that she must go back, even though there was now nothing to go back to but the dear memories of an empty, still house. She was going back—going home— to wait for Jerry. Surely he would be as anxious, as homesick as she, as wounded perhaps. And when he came she would greet him and he would forgive. Life would begin anew.

But it was not to be. For the very hour that she was making her final surrender, the wires that bridge the ocean were ticking off a sensational message. They were saying that over in a Vienna laboratory a young American doctor, a big, simple gray-eyed chap from some little cornfield country town in America, had made a great discovery.

Already scores of folks were being cured, the most famous patient so far being the charming daughter of a well-known American statesman. Rumor had it that it was love for the beautiful invalid that had driven the young doctor night and day to seek the cure until at last he found it.

When Mollie read that cabled despatch, she knew that for her the best of life was over. And she saw, of course, the one thing left for her to do. So when the excitement of the new discovery had quieted down and people were watching other things, she very quietly gave Jerry his freedom.

This done she sat down amid the ruins and laughed a little madly. She had pitied herself in those lovely, lost days; had talked bitterly of her great talent dying perhaps without one chance of being put to the world's service.

Now she was successful. People told her so and borrowed her money. But compared to Jerry high up on his shining mountain top? No, no. Her business, so an ironical Fate had decreed, was to record Jerry's glory. She worked in dirty, dusty newspaper offices, read and recorded the ticking cable messages Jerry worked among the stars, in clean, healing solitudes.

So Mollie sat amid the ruins that day and laughed bitterly at herself and her old stupidity. For both their sakes they must never meet. That was why she had fled so frantically from London.

And now, Jerry was here—on the same boat. She had seen him. And he had told her not to worry—"about any thing."

Well, she wouldn't. Now that there was no need of obeying she would obey him and worry not at all.

With that she fell asleep and slept right on to six of the clock of the new morning. The fog was gone, the heavens wide and the ocean a glittering wonder of blues, grays, greens and full of gentle- silvery little white ruffles.

For the first time in four long years she felt glad and told herself stoutly that se was happy. She raised her arms and stretched them out to the wonderful old world that lay about her.

"Oh, glory, glory! Isn't it beautiful!" she said to the sailor boy who was washing the deck. And he smiled with her and nodded. And just then Jerry came around the corner looking as new as the morning. She stepped to the rail to give him free passage, but he stopped at her side and looked squarely into her eyes.

"Your headache is all gone, isn't it?"

"Yes," she laughed. "I did just what you told me to and here I am—well."

A little pain clouded his eyes for a minute and he started to say something, but changed his mind and stood quietly beside her looking over the smiling waters. She was trying to gather courage to say what she knew she must sooner or later.

"Jerry," she said at last gravely and frankly, "where is your little girl?"

"She's down in the cabin pretty sick." Then aftera while he added, "How did you know about—her?"

"I met Jack just as he was leaving for his boat. He told me."

Mollie was suddenly silent. But after a bit she made herself say, "Hadn't you better—couldn't someone—" Then she remembered and flushed painfully.

"No," he said curtly, "she wants to be alone."

Suddenly he said:

"Mollie, I can't wait to get home. I want to see if there is a pair of bluebirds in that old birdhouse I made and if the clover's as thick in the back meadow as it used to be and if that old fence near the barn is still standing."

Home to her now meant two rooms in a tall brick structure on a dully respectable street. But she strained the pain from her voice before she answered:

"I expect it will be all there Jerry."

"It's four years," mused Jerry, and his voice was so full of homesickness and remembered pain that Mollie's throat ached. "Four years. Mollie do you remember the evenings when we wouldn't have lights and the moonlight came in hrough the window and lay in squares across the living-room floor? And our grate-fire with a pine knot glowing and everything absolutely perfect and still, and the old clock ticking on the stairs?"

Would he never stop?

"Mollie, girl, it's great to travel and knock about odd corners of the world; to see and know things. But there's nothing, nothing that's ever as fine as the road back home. And when I lost that—and lost—you——"

In his old dear way he was explaining to her the little bride down in the cabin, how he came to get her, to still the longing, to ease his heartache. And Mollie understood and bore the little bride no ill-will.

Nevertheless her throat ached with smothered sobs. Yet she dared not show her pain, for if she did, Jerry would surely comfort her in the old sweet way and there wss the girl to think of, sick and alone in her cabin.

Jerry was continually forgetting the little bride. And Mollie could understand that, too. With all his thoughts back there in the old home. For the moment he had wiped out the years and was with Mollie again in the old white house.

This worried her at first and at every opportunity she brought in the bride.

"Is she all well now, Jerry—cured?" For the bride was, Mollie knew, the noted statesman's daughter.

"Why, yes, she's all right. She'd get over her seasickness if she'd only come up on deck. But she won't. Reads and sort of dreams in the cabin. Oh, I know how she feels and so I let her alone." Jerry smiled tenderly and Mollie felt her heart cramp for one blinding second.

"Oh, I tell you Mollie," and Jerry laughed a little, "I've learned a lot of things about women. If I'd known what I know now, you'd never have gone."

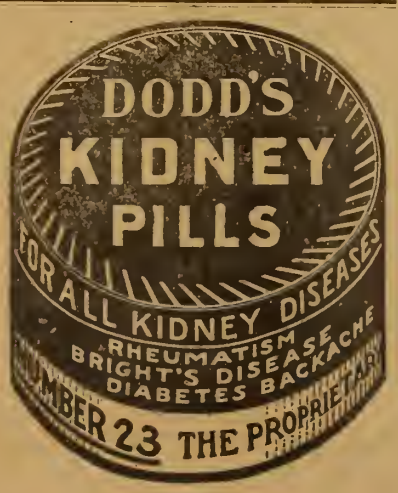
"No, Jerry." She hastened to shoulder all blame. "I was a fool, and there is no salvation for such."

Jerry's eyes darkened with pity and he gave her what he thought was rare comfort when he said:

"Ah, well—it's over and done with now. And we're going back, all of us. That's everything. Why, this is the road back home Mollie.

And she, knowing there was no such road for her, lifted the cup to her white lips and drank.

After that, things were easier. And when the bride came up at last, Mollie sat down beside her and talked, talked naturally and bravely and with a fineness and sparkle that surprised even herself. Jerry found them together



ROYAL YEAST CAKES

Now that the new government standard flour is in general use, the quality of the yeast you use is more important than ever. Use Royal Yeast Cakes. Their quality is absolutely reliable. Bread made with Royal Yeast will keep fresh and moist longer than that made with any other.

Doing Our Bit

The most patriotic service we can render is to continue to fit young people to take the places of those who have enlisted.

There will therefore be no Summer Vacation this year. One of the principals and other senior teachers always in attendanace.

Students can enter a tany time.

Moncton, N. B. Truro, N. S.

And Molile smiled.

They were all sitting together when the shock came. There was no warning. just a terrible roar, then flying splinters and flames leaping high.

They stared stupidly for a few seconds, then Jerry said quietly, "There will be just enough time to get your valuables. I'll get the lifelbelts."

Five minutes later they were being crowded into life-boats. There was not a scream or a hint of panic anywhere. The officers were giving orders a little more sharply than usual and their faces were as white as their uniforms.

The ocean sparkled. the flames crackled and not a living soul made a sound until it was discovered that two life-boats had been splintered by the explosion and that there would be no escape for the officers and some of the men passengers. Then it was that the wail went up. Wives and babies screamed for their husbands and fathers.

Jerry helped the little bride into the boat, smiled down at her reassuringly and then turned to Mollie who had hung back and was now the last woman on board.

"Thank God, there is room for the last woman," murmured the relieved captain, himself stretching out hands for Mollie.

"No, captain, I stay right here. Give my place to Dr. Collins, here. Jerry," she begged, " you must—she'll need you,"

But Jerry smiled and shook his head and suddenly Mollie smiled too, and when the captain saw that smile he swore for he knew that his ship would go down with a woman on board.

They stood at the rail and waved to the bride and she waved back.

"She will be safe and happy," Jerry said and then he looked at Mollie in a way that made her forget all fear forever. "You should have gone, Mollie, girl, but I' mglad you stayed."

"Oh, Jerry, Jerry," she laughed. "I had to stay. Don't you see that it was my last chance to travel the road back home? We'll travel it now together."

"Yes—together," and he made sure that her life-belt was snugly strapped for he saw that in another second they would have to jump.

Mollie lay white and still in a steamer chair on board "The Silversand." Jerry was beside her. They had been almost the first to be picked up and Jerry was none the worse seemingly for his plunge. But Mollie puzzled him.

"Why, Mollie, girl, cheer up—rouse yourself. You're not hurt. There isn't a scratch o nyou. It's just the shock that's knocked you out. Fight it! In a few hours we'll be standing in New York taking the first train home."

"Home—home!" sudednly sobbed Molile; "that's where I was trying to go. Why couldn't they let me go alone? Why—"

"Why, Mollie," and all at once Jerry looked stricken, "don't you want to go home with me?"

"Jerry, boy—there's your bride—how can you——"

"My bride—my bride-" Jerry fairly screeched, then sat up and looked strangely at Mollie.

"My God, girl, have you been thinking all the way over that that child was my bride? You told me you had seen Jack; that you knew. Why, that girl is nothing to me; just a former patient. Jack married her in Berlin four months ago and they were starting for home. Wanted to get a home settled for the little one that is coming to them soon. Then his paper ordered him to Constantinople. He couldn't take her off there with him. I was just going home. I had been her physician. So he asked me to look after her."

Mollie was smiling foolishly and then she quietly and beautifully fainted away.

When the boat nosed her way into the home harbor, Jerry and Mollie stood at the rail prepared to be the first down the gang plank.

"We are going to stay just long enough to be married—that's all," he told her. "Tomorrow, girl, we'll be together—on the road back home."

STIR YOUR TEA

Stir the pot of Tea a minute or so before pouring. This evenly distributes the Tea essence that has been drawn from the leaves, but is lying mostly at the bottom of the pot. You will then get the full flavor from your Tea. And if it is KING COLE Orange Pekoe, note when you stir, the delightful fragrance of the infused leaves. Note also the rich color of the Tea when poured—both indications of unusual quality.

KING COLE Orange Pekoe is different from other Teas.
ASK YOUR GROCER FOR IT BY THE FULL NAME
SOLD IN SEALED PACKAGES ONLY.

THE EXTRA in CHOICE TEA

On the darkest road, on the blackest night, It shows the time in figures of light.

Ingersoll Radiolite
The 24-hour-a-day watch

BY day your Ingersoll Radiolite shows the correct time like any other good watch. And at night it shows the correct time in the dark.

Think of the convenience of a watch that shows the time in the blackest dark—when you awake at night, during evening chores, night driving and so on.

Real Radium in the substance on the hands and figures, does it. The luminosity is guaranteed for the life of the watch by this Company, which has been in business 25 years and sold 50 million watches.

If you're in the barn or the garage after dark—there's the correct time without the aid of a dangerous match.

Radiolite Models - $2.50 to $5.00
Other Models - - $1.50 to $9.00

If you can't get the Ingersoll Radiolite from the dealer, send us his name and we will see that you are supplied.

ROBT. H. INGERSOLL & BRO.
128 Bleury Street Montreal

SUFFERED WITH KIDNEYS FOR THREE YEARS.

70 YEARS OLD AND CURED.

Late in life the body is likely to show signs of wear. Often the kidneys are the first organs to weaken. That's why many elderly folks suffer from backache, lame back, poor eyesight, rheumatic pains, gravel, dropsy and inability to control the urine.

Doan's Kidney Pills have made life more comfortable for thousands of old folks, as they stimulate the kidneys and tend to alleviate rheumatic joints, backache and too frequent urination. When past middle age it is a good plan to use Doan's Kidney Pills occasionally, just to keep the kidneys healthy.

Mr. John Cameron, Baldwin, Ont., writes: "I was troubled with my kidneys for three years and tried several doctors. I got better for a little while, but the same trouble came back. A friend told me to get a box of Doan's Kidney Pills, and before I had taken them I felt better and kept on until I had taken five boxes. I am seventy years old, and had given up that there was any help for me, but thanks to "Doan's" I have been cured."

Price 50c. a box, at all dealers, or mailed direct on receipt of price, by The T. Milburn Co., Limited, Toronto, Ont.

See that our trade mark a "Maple Leaf" appears on the wrapper.

FRESH VEGETABLES IN THE DIET

The importance of fresh vegetables in the ordinary diet has, we think, been overlooked in the past by many farmers; their greater use may be urged on two grounds, as partial substitutes for meat and wheat in these war times and as wholesome, palatable, attractive adjuncts to the day's bill of fare, supplying mineral and other substances essential to good health.

As savers of meat and bread.—It cannot be claimed that fresh fruit and vegetables may be used to replace entirely the staple and more substantial foods, meat, milk, cheese, bread, for as a class they are poor in the body building nutrient (protein) and in fat, the most important of the nutrients in heat and energy production in the body. Nevertheless many of these have a distinct value as savers of meat and bread and in these times it is desirable, if not imperative, that they should be so used.

Prominent among the vegetables that may be employed to advantage to partially replace meat are **beans and peas.** These, unlike vegtables in general, are particularly rich in protein, though it must be admitted that their proteins is not in equal value in human nutrition with that of meat. Alone or in combination (milk-vegtable soups, chowder, souffe or omelet) they make nutritious, wholesome and palatable dishes, easily permitting a reduction of 25 per cent in the meat account.

Potatoes can be advantageously used to save bread; indeed, in spite of their somewhat low protein content they stand out on this continent as the most important substitute of the cereals. Roughly speaking, a potato of 4 ounces will furnish as much nutriment as an ounce of bread, though the latter will be slightly the richer in protein. They are essentially starch and being highly digestible when properly cooked may well be employed to furnish a large part of the daily ration for the production of heat and energy in the body. By the free use of potatoes, the quantity of flour ordinarily consumed—as bread, buns, etc.., may be easily cut down 25 per cent, without any discomfort to the family. They are cooked with practically no loss of nutritive value by boiling or baking in their skins. The outer skin with its immediately underlying layer (peel) is much richer in protein and ash constituents than the body of the potato and hence furnishes in the baked tuber (previously well washed) not only delicious but nourishing food.

Corn on the cob might also be mentioned among the vegetables of high nutritive value; it is no less nourishing than enjoyable for several weeks in the season it may well furnish the chief dish at one meal in the day. Beets, parsnips, artichokes, carrots all possess distinct food values.

Hygenic value. The food value of a few of the more important vegetables has been briefly mentioned. Of still greater value is the part that green fresh vegetbles play in the maintenance of good health. They contain certain salts and mineral compounds as necessary for our well being as the nutrients in our food. In this connection we may quote from an eminent English authority on foods, who says "It is considered essential that a fresh vegetable, such as cabbage, cauliflower, potato, lettuce or other salads (or fruit) should constitute a portion of at least one meal a day. The mineral salts of fresh vegetables render the blood and urine more alkaline and their fibre acts as a stimulus to the movements of the alimentary canal, promote intestinal secretion and counteracts a tendency to constipation."—Frank T. Shutt, Dominion Chemist.

Let Nature Clear Your Blood

With pure, rich blood—a healthy stomach—and an active liver—you may laugh at disease, and, you may have all three by taking

Dr. Wilson's HERBINE BITTERS

This splendid blood medicine—made of old fashioned herbs—gives the system a regular "spring housecleaning"—regulates liver and bowels—cleanses the blood of all poisonous matter—tones up the nerves—and gives strength, vigor and a feeling of good cheer to the whole system.

At most stores. 25c. a bottle; Family size, five times as large, $1.

A DRY SHAMPOO

Many people make the mistake, when the hair is excessively oily, of washing it too frequently. Now, shampooing the hair does take off the oil from the scalp, and from the hair, and it also stimulates a new supply of oils—which is as it should be. But weekly washings are apt to take the life out of the hair. Three weeks is best for the soap and water shampoo, in some cases two weeks.

Excessive oiliness denotes an unhealthy condition and should be treated. Meantime, as the hair gets too oily to do up well, a dry shampoo may be used to absorb the oils.

Plain, everyday corn meal, coarsely ground, is wonderful for this. . Spread a sheet of newspaper on the floor, or on a table; take a handful of cornmeal and work it through the hair; take another and another, shaking it through the hair and massaging the scalp; then brush the hair till it is clean and glossy again. You will be surprised at the dirt on the meal when you gather up the paper.

Orris powder is good, too, and rather fragrant. To make this dry shampoo take:

Corn starch, 1 pound; powdered orris, 2 ounces; any perfumed oil, 10 drops.

Keep this in a sifter top can. Sift through the hair, and massage; brush out again. Neither of these powders clogs the scalp much, but they should be brushed off thoroughly, even so. A lot of powder on the scalp keeps it from breathing.

The hair should be shaken, and brushed and shaken again after a powdering (to bring back the natural gloss).

COVERING THE BRIM OF A HAT

When the brim of the hat is of uniform width and not too wide, a bias strip may be used for covering it. If the same material is to be used on the upper and under side, it will not be necessary to have a seam at the edge

The strip must be cut on the true bias and be about two inches wider than twice the width of the brim. Fold the strip through the middle lengthwise and mark the centre with a line of uneven basting. Stretch the material along the folded edge; slip over the brim, keeping the line of basting at the edge and pulling the material snug. Pin in place, putting the pins in at right angles to the edge.

When the strip has been fitted around the brim, mark the place of joining. Remove the pins, take off the material and baste and stretch the seam. Be sure to have the seam with the straight of the goods.

Put in the bias over the brim again and pin in place. Have the line of basting at the edge and the seams at the sides but toward the back. Baste near the edge catching the material on both the upper and under side.

Run a gathering thread near each of the cut edges. Pull the material from the edge of the brim toward the crown and adjust the gathers evenly. First pin and baste the material in position on the upper side, taking the stitches just beyond the bend where the brim joins the side crown. Adjust and baste the under side pulling the material snug.

NONSENSE A GOOD THING AT THE SUPPER TABLE

The fashions in housedresses would seem to have been made for the busy housewife. These straight up-and-down frocks slip on so easily and so quickly and are so shipshape when on that one can dress in a moment. The rather loose frock, made in one piece (waist and skirt fastened together at the girdle line) or joied by snap fasteners if there is any good reason why two parts are more convenient, does away with all bother about hunting and adjusting belt, placket and trimmings—it is all in in one and goes on with about two minutes or less of adjustment.

And it hangs up in your closet on its coat hanger all ready for the instant's rush. Try it and see how much nerve strain it saves you. With a nice big apron you can go into the kitchen and get supper and come out looking as fresh as if you had been sitting in front of the fire doing your war-knitting instead of hustling to get things ready for the family onslaught.

In the question of table conversation a tremendous power lies in the hands of the mother in the directing of family talk. If the mother is indifferent and too tired to join in the conversation the children will monopolize it and descend to trivialities, nonsense or bickering often.

A little jolly nonsense is a mighty good thing at the supper table, and the good jokes you can cull out of the magazines will ward off many a quarrel between Jack and Julia if skilfully applied. But bickering has no rightful place in the family circle. One wise mother I knew used to say, when discussion got too warm, "Can any of you tell me the price of white mice today?" and when inserted into the talk in her sweet, calm voice this question would bring, as she expressed it, "a paragraph on a new subject."

Don't be afraid to ask John's opinion about the women's club politics; he'll soon find them alomst as interesting as his own Civic Club ones if you tell him of the amusing things that happen and so keep young or grow old gracefully together.

My Limbs Would Twitch

AND WAKEN ME—UNABLE TO REST OR SLEEP, I WALKED THE FLOOR IN NERVOUS STATE — WHEN SPECIALISTS FAILED I FOUNN A CURE

This is the kind of a cure that has set Windsor people thinking and talking about Dr. Chase's Nerve Food. The action of this food cure is so radically different to the usual treatment for the nerves that everybody wants to try it. Gradually and certainly it nourishes the starved nerves back to health and vigor and the benefits obtained are both thorough and lasting.

Mrs. M. Smithson, 27 Arthur Street, Windsor. Ont., writes: "I was suffering from nervous breakdown, which was caused by a shock when fire broke out in the adjoining house. My nerves were in such a state that, after going to bed I could not get my nerves quietde down sufficiently to go to sleep. I used to get up and walk around the room, or go downstairs. Even when I would be dropping off to sleep my limbs would twitch and waken me. I used to have cold, nervous night sweats, sometimes would become unconscious and lie that way for quite a little while. I was always cold and it seemed impossibde for me to get warm or keep warm. When on the street I would see two or three objects at once, and did not wont any person to speak to me or bother me. Any little noise irritated and annoyed me very much. I had consulted specialists and tried many remedies during this time, but could not gain relief. At last I tried Dr. Chase's Nerve Food, and bemore long could see that this treatment was proving of benefit. I am now feeling so much better that I can go out on the street without any dijculty, can go across the river and go about the same as usual. I sleep well at night, and am feeling more like myself every day. I am pleased to be able to write you to tell you how much good the Nerve Food has done me. It has strengthened and built up my whole system. I am recommending it to everybody I find suffering from nervous disease of any kind."

Dr. Chase's Nerve Food, 50 cents a box, a full treatment of 6 boxes for not be talked into accepting a substitute. Imitations only disappoint.

RYE MEAL BISCUITS

Stir a cake of compressed yeast into one-fourth a cup of scalded and cooled milk; add one cup of scalded and cooled milk and one and a half cups of sifted bread flour, and mix to a sponge; beat thoroughly and set aside to become light. Add a scant fourth of a cup of melted butter, one-fourth cup of molasses, half a tea spoonful of salt and one and one-fourth cups of sifted rye meal. Mix thoroughly, cutting the dough through and through with a knife. The dough is too soft to knead. When light, with buttered fingers, shape into sixteen balls and set them close together in a baking pan. When again light bake

I bought a horse with a suposedly incurable ringbone for $30.00. Cured him with $1.00 worth of MINARD'S LINIMENT and sold hom for $85 00. Profit on Liniment $54.

MOISE DEROSCE.
Hotel Keeper, St. Phillippe, Que.

about twenty-five minutes; brush over with white of egg or beaten yolk mixed with milk, dredge with granulated sugar and return to the oven to set the glaze. The biscuit may also be glazed with milk without either the white or yolk of egg.

The bran from the rye meal, from which extraneous matter has been removed, may be used. Graham flour may replace the rye meal. Sugar may replace the molasses or all sweetening may be omitted by adding an extra one-fourth of a cup liquid.

EAT AND BE HAPPY

Thomas A. Edison, the greatest inventor in the world, enjoying robust health in his seventieth year, gave this piece of awvice to his fellow citizens:

"Eat the best food, bnt eat less of it. And eat it properly. One-third of tl e average amount of food consumed is a sufficent amount. I eat a quarter of what the averagfe man does. I know because I see it on my own table."

The amount of food eaten is a matter of each individual's requirements. But it is higly probable that the quality of food and the quiet enjoyment of it has something to do with the long and useful life of the wizard of electricity.

There is some thing back of the enjoyment of food. Experts tell us that a laugh at the table adds a day to a life. Dry bread and onion, and a bottle of cogee, are sufficent susteance for the Italian laborers at work on the roadside. They eat in happy companionship, and with the light-heearted jests of their race.

Let us be happy when we eat. There is food for thought in that.

DON'TS FOR THE HOMEMAKER

1. Don't save your best preserves or your sunniest sleeping room for company because who is better company than your own family?

2. Don't ever be so tactful that members of your family will suspect that they are being managed.

3. Don't dictate, even to children, if you can help it. Suggestion is so much better.

4 Don't fail to voice your appreciation whenever any of the family try, even in the smallest way, to lighten your labor.

5. Don't neglect your hair. In other words, adapt your hair-dressing as becomingly to yourself as the styles will permit. No one will appreciate it more than the family. Many a homemaker takes pride in her ufrnishings and even her own dress, but forgets to change her "pug" from the style of ten or fifteen years ago.

6. Don't economize on sleep. If you are up the night before, manage to take a little nap, if ever sa brief, the next day. Plenty of sleep is like oil to an engine.

7. Don't miss reading something uplifting every day. There is always five minutes to spare. If the reading matter is on hand, and, it may be, that five minutes reading will save you an hour of despondency or fatigue.

THE NEW TABLE MANNERS

(From the U. S. Food Administration)

Are you familiar with the latest rulings in war etiquette? And especially the new table manners? Here are a few excerpts from the latest revised 1918 code. It's a war emergency edition, and rebebzer that for every rule "there's a reason."

Economy luncheons are now in vogue. Bread is served on a breadboard and cut as wanted. Everything is passed, and it is correct for each guest to take only what she is sure she wants and to eat all she has contracted for. The cleaner the plate, the better for the manners!

At dinner bread is dispensed with entirely. Likewise butter. It is correct to tip your soup plate to be sure of the last drop. Waste not, want not.

The meat is carved at the table that the guests may be served a second time rather than waste too large a first portion.

When the new war dishes are passed, sample them. Be willing to try everything once. You may like them. But if you are ogered food that you are sure you cannot eat, it is quite au fait to refuse it point blank. Your hostess will understand that it is merely the new war table manners. No watse is the or6der of the day.

It is no longer boorish to wipe up your gravy with a piece of bread and thus conserve butter.

If unable to accept a dinner invitation, you should send your regrets before your hostess has done hed marketing. For these days of close buying or food stugs.

At the reception, lunch or tea it is no longer good form to toy with one's food and then send it back to be thrown out. For this reason it is becoming more and more popular to serve refreshments whenever possible, in buget style. The guest is then put upon his honor not to take more than he wants.

At hotels or restaurants it is perfectly consisten with the order of the day to use your husband's remaining bit of butterthat would make your bread "just come out even."

Don't waste sugar. If two lumps or sugar have been put at the side of your coffee and you do not use sugar in youf coffe at all, better return them to your hostess.

The standard of wealth and social position is no longer gauged by what people can afford to waste. Some years ago a wedding took place at a summer resort on the New England coast, and the elaborateness of that affair is still a fresh memory in those parts. A thrifty New England housewife who was describing the splendor of that repast led up to her climax by saying: "And what do you think? Why, the next morning they carried out two whole barrelfuls of garbage!" But that was "before the war." Today, waste on any such scale would be both unpatriotic and unmannerly.

DATE CUSTARD PIE

1 Cupful Finely Chopped Dates
½ Teaspoonful Salt
2 Cupfuls Milk
4 Tablespoonfuls Butter
4 Tablespoonfuls Flour
3 Tabelspoonfuls Sugar
2 Eggs

Mix the salt with the flour and stir into the butter, which has been melted. Add the milk an stir over a moderately hot fire until it comes to the boiling point. Add the dates and the sugar. Now move the vessel to the back of the stove and let the mixture simmer until the dates have softened. When slightly cooled, add the beaten yolks of the eggs and pour into a lined pie-tin after the pastry has been allowed to harden. Use the whites for the meringue, adding after the custard has set.

PRUNE CUSTARD PIE

1 Cupful Seeded Prunes
3 Tablespoonfuls Sugar
1 Tablespoonful Corn-starch
1 Salt-spoonful Soda
2 Eggs
1 Cupful Sour Milk
Pinch of Salt

Stir the sugar and salt into the beaten yolks. Add the milk to the corn-starch into which the soda has been sifted, taking care that it does not form lumps. Add the two mixtures together and stir in the prunes, which must be chopped finely so that they will mix thoroughly. Pour this over the pastry and bake. Use the whites for meringue, flavoring with lemon-juice.

Carry Lemons on Your Automobiling Trips and jaunts into the country, if you are suspicious of the purity of the drinking water. The juice of a lemon squeezed into a glass of water will purify and make it safe for drinking.

Economy Jar Caps may be taken from the jars by placing a hot iron on them and turning until all the adhesive material is softened, instead of puncturing the cap as directed. Caps may then be used again on jars used for jam or pickles not needing to be sealed.

In Making Gems, you can save waste and labor by melting the shortening in one of the pans in which you are intending to bake the gems; then, with a bit of soft paper, swab the other pans from the first.

Paper Flour Sacks make excellent ice blankets for covering the ice in the refrigerator. By doing this the ice bill will be greatly lessened. Newspapers may also be used with good results.

To Boil and Bake With the Same Heat from your oil stove, bake in the rack of your oven and boil in lower part, near the fire. This not only economizes on fuel, but improves the baking quality; it also boils faster and better than in an open kettle.

Old Suspenders, Washed and Ironed, make splendid inside belts for skirts. Since they are narrow, lap two edges together and stitch them on the machine. They do not get flimsy after washing, as regular belting does.

Your Lettuce Will Not Wilt and therefore have to be discarded if you will wash it thoroughly and keep it in an earthen jar tightly covered.

When Children's Ribbed Stockings are hopelessly worn out, unravel the remaining parts of the legs, wind the cotton or wool on a spool and use for darning other stockings.

In the Fields
Wear the Sturdy
FLEET FOOT SHOES
and enjoy the easy comfort which these economical shoes give.
FLEET FOOT
is for work as well as for play. Staunch, sturdy styles like the "WORKMAN" and "EVERY-DAY" stand right up to any farm work—yet are light and easy, and enable you to tramp the fields all day without the feet getting over-tired.
The leading Shoe Stores have FLEET FOOT styles, shapes and sizes for every member of your family—for work or play.
None genuine without the name FLEET FOOT stamped on the sole. Look for the name.

DON'T WORRY

Worry is the most popular form of suicide. Worry impairs appetite, disturbs sleep, makes respiration irregular, spoils digestion, irritates dispositions, warps character, weakens mind, stimulates disease and saps bodily health. It is the real cause of death in many instances where some other disease is named in the death certificate. Worry is mental poison; work is mental food.

When a child's absorption in his studies keeps him from sleeping, or when he tosses and turns from side to side, muttering the multiplying table or spelling words aloud, when sleep does come, then that child shows he is worrying. It is one of nature's danger signals raised to warn parents and in mercy the parents should take a firm stand. The burden of its daily task should be lightened, the tension of its concentration should be lessened, the hours of its slavery to education should be cut short.

When a man or woman works over in dreams the problems of the day, when the sleeping hours are spent in turning the kaleidoscope of the day's activities, then there is either overwork or worry, and most likely it is the worry that comes from overwork. The Creator never intended a healthy mind to dream of the day's duties. Either dreamless sleep or dream of the past should be the order of the night.

When the spectre of one grief, one fear, one sorrow, obtrudes itself between the eye and the printed page; when the inner voice of this irritation memory, or fear, looms up so loud as to deaden outside voices, there is danger to the individual. When all day, every hour, every moment, there is the dull, insistent, numb pain of something that makes itself felt through, above and below all our other thinking, we must know that we are worrying. Then there is but one thing to do—we must stop that worry; we must kill it.

Worry is forethought gone to seed. Worry is discounting future sorrows so that the individual may have present misery. Worry is the father of insomnia. Worry is the traitor in our camp that dampens our powder, weakens our aim. Under the guise of helping us to bear the present, and to be ready for the future, worry multiplies enemies within our own mind to sap our strength.

Worry is the domination of the mind by a single vague, restless, unsatisfied, fearing and fearful idea. The mental energy and force that should be concentrated on the successive duties of the day is constantly and surreptitiously abstracted and absorbed by this one fixed idea. The full, rich, strength of the unconscious working of the mind, that which produces our best success, that represents our finest activities, is tapped, led away, and wasted on worry.

Worry must not be confused with anxiety, though both words agree in meaning, originally, a "choking," or a "strangling," referring, of course, to the throttling effect upon individual activity. Anxiety faces large issues of life seriously, calmly, with dignity. Anxiety always suggests hopeful possibility; it is active in being ready, and devising measures to meet the outcome. Worry is not one large individual sorrow; it is a colony of petty, vague, insignificant, restless imps of fear, that become important only from their combination, their constancy, their iteration.

When the death comes, when the one we love has passed from us, and the silence and the loneliness and the emptiness of all things makes us stare dry-eyed into the future, we give ourselves up, for a time, to the agony of isolation. This is not a petty worry we must kill it, as it kills us. This is the awful majesty of sorrow that mercifully benumbs us, though it may later become, in the mysterious working of omnipotence, a rebaptism and a regeneration. It is the worry habit, the magnifying of petty sorrows to eclipse the sun of happiness, against which I here make protest.

To cure worry, the individual must be his own physician; he must give the case heroic treatment. He must realize, with every fibre of his being, the utter, absolute uselessness of worry. He must not think this is common-place—a bit of more theory, it is a reality that he must translate for himself from mere words to a real, living fact. eH must understand that if he spent a whole series of eternities in worry, it would not change the fact one jot or tittle. It is a time for action, not worry, because worry paralyzes thought and action too. If you set down a column of figures in addition, no amount of worry can change the sum total of those figures. That result is wrapped up in the inevitability of mathematics. The result can be made different only by changing the figures as they are set down in that column.

The one time that the man cannot afford to worry is when he does worry. Then he is facing, or imagines he is, a critical turn in affairs. This is the time when he needs one hundred per cent of his mental energy to make his plans quickly, to see what is his wisest decision, to keep a clear eye on the sky and on his course, and a firm hand on the helm until he has weathered the storm.

There are two reasons why man should not worry, either one of which must operate in every instance. First, because he cannot prevent the results he fears. Second, because he can prevent them. If he is powerless to avert the blow, he needs perfect mental concentration to meet it bravely, to lighten its force, to get what salvage he can from the wreck, to sustain its strength at this time when he must

A SERVICE FLAG WITH MANY STARS

Pathe Freres, the World-Renowned Makers of Phonographs and Moving Picture Films, Have 2,080 Stars in their Service Flag.

Mr. Ferdinand Zecca, the new Director General of Productions, who arrived recently from Paris, states that more than 2,000 French, English and Italian employees of Pathe Freres have served in the ranks of the Allies as officers, non-commissioned officers and privates, and that more than 200 died on the battlefields.

More than 500 have been decorated for bravery.

A large number have been wounded and released from service, and have returned to the positions they held with Pathe Freres before enlisting.

More than 80 men have responded to the call to the colors on this continent, and the list is rapidly growing.

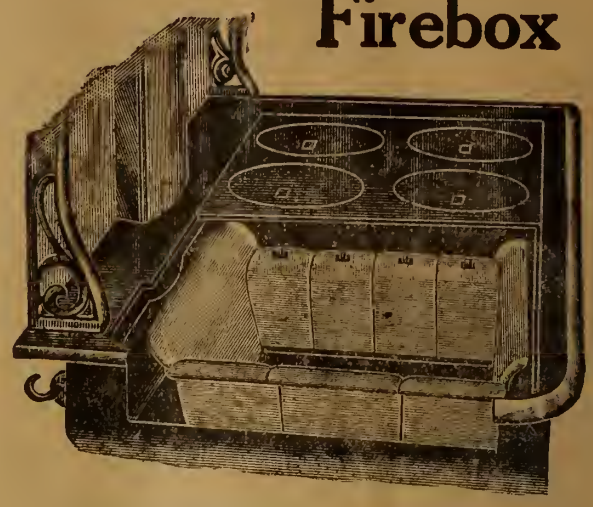
FIRST AID IN THE KITCHEN

Mends Leaks in Graniteware, Tin, Aluminum, etc., in two minutes without tools. Saves a kettle for half a cent. At dealers or from us, 15 cents.

Vol-Peek Co., Box 2024, Montreal, Can.

VOL-PEEK

The Stretchable Firebox



Durability in a firebox depends mostly upon its ability to expand when hot and to contract when cold, without cracking.

Ever notice that steel rails are laid with a space at the ends—it is wider in winter than in summer. That space allows for stretching in the warm summer weather.

Kootenay fireboxes are made of nine pieces of pure semi-steel. They can expand without cracking. That is why Kootenay fireboxes last so long. If you do have to change a piece it comes out with a tap of a hammer—no bolts, no rivets or other fastenings—just good accurate fitting.

"Service in the Kitchen."—Booklet Free

This is only one of the many features of the Kootenay Range described in a beautiful little booklet, "Service in the Kitchen," which will be mailed free on request. It tells all a woman wants to know about a range before she buys it.

Spanking Doesn't Cure!

Don't think children can be cured of bed-wetting by spanking them. The trouble is constitutional, the child cannot help it. I will send **FREE** to any mother my successful home treatment, with full instructions. If your children trouble you in this way, send no money, but write me to-day. My treatment is highly recommended to adults troubled with urine difficulties by day or night. Address

plan a new future. If he can prevent the evil he fears, then he has no need to worry, for he would by so doing be dissipating energy in his hour of need.

If man does day by day, ever the best he can by the light he has, he has no need to fear, no need to regret, no need to worry. No agony of worry would do aught to keep him. Neither mortal nor angel can do more than his best. If we look back upon our past life we will see now, in the marvelous working of events, the cities of our greatest happiness and of our fullest success have been built along the rivers of our deepest sorrows, our most abject failures. We then realize that our greatest happiness or success would have been impossible had it not been for some terrible affliction or loss in the past—some wondrous potent force in the evolution of our character or our fortune. This should be a wondrous stimulus to us in bearing the trials and sorrows of life.

To cure oneself of worry is not an easy task; it is not to be removed in two or three applications of the quack medicine of any cheap philosophy, but it requires only clear, simple, common sense applied to the business of life. Man has no right to waste his own energies, to weaken his own powers and influence, for he has inalienable duties to himself, to his family, to society, and to the world.

The Matter of Worrying.

There is just one thing more enervating than worrying too much, and that is not worrying enough. The philosophy in the advice DON'T WORRY is not the philosophy of practical people, but of newspaper physicians, beauty doctors, useless centenarians, and cheerful cherubs generally. One opens up the calendar for the new year and the motto on January 1st whn bills fall due, is DON'T WORRY. One break a leg on the icy sidewalk and lies abed when business is urgent, and the nurse, discovering a degree or two of perfectly justifiable fever, says sweetly, now DON'T WORRY. Was ever advice so untimely?

If love makes the world go 'round, it is worry that makes it forge ahead. To the Anglo-Saxon makers of our tongue, to worry meant to strangle, to take the wolf at the door by the throat and choke him, not simply look timidly at him through the keyhole and deplore his presence. If a mother does not actively worry when her children fall ill, the chances are that she will allow the unsanitary conditions which brought them to this pass to continue. If a father does not actively worry over his growing boy he is likely to have a far severer kind of worry to indulge in when the boy reaches manhood. It is a housewife's worrying over the pennies that leaves the pounds free to take care of themselves.

True serenity is not the negative result of not worrying, it is the positive result of fighting, and comes after, not before the battle, "Job's comforters," for all our meering, were his good friends. They found him disconsolate upon an ash-heap, his mind an amorphous fog of self-pity. Had they told him not to worry he would, doubtless, have sat there, passively non-worrying to the end. As it was, before they got through with him he was justifying himself to his Creator in good, clear energetic terms that promised well for the future.

When the schoolboy says "I should worry", he comes nearer to the truth than he knows; and it is only because he has already worried—worried his way through problems to their solution, and strangled the wolfish questions on examination papers into silence, with a decent display of knowledge—that he can voice his present unconcern so cheerfully. Were the business men to stop to the same slang phrase—perhaps he does—he would yet know in his soul that he can only get to the top by worrying his way there.

The man who doesn't worry is the type of man who doesn't pay his rent. The woman who never worries sits passively rocking while her children run at large. But your true and capable workers asks for no comforting palaver. No rocking-chair for him. From much strangling of wolves he has become an expert wrestler. He is no tat a loss in a catastrophe. For he is like one who has stooped in order that he may leap. His muscles are taut, his vision clear, and for him, "if the sky falls, there will be dathcing of larks." For non-worrying Micawbers nothing turns up, but this man will worry his bright, undaunted way to the unattainable.

THE YOUNG FOLKS

The children go loving this good old world,
Just loving it simple and true,
Filling it full of their own sweet dreams,
And loving it—that's what they do.
To them its a place to be happy in,
And they view it with shining eyes.
O grown folks, weary and wistful and worn,
Are not the children wise?

We grope for the mean and the selfish things,
They hold to the dream and the play;
We toil for the money that leaves us poor,
They're rich in the sunlit day.
We hate and suffer, they love and enjoy,
All under the self-same skies—
O grown folk living a life so bare,
Are not the children wise?

HOUSEHOLD HINTS

To take up a carpet properly, first sweep and wipe it, then remove all tacks, and carefully fold one-half the carpet back upon the other. Sweep the exposed under side with a stiff broom well dampened, fold again in half and sweep the under side. Repeat until the whole carpet is in a handy pile, which can be lifted and taken away. Rugs or carpets should not be dragged in moving them.

In cleaning bureau drawers it is a good plan to wipe them out with a damp cloth and then follow with a linen cloth wet in alcohol. This will dry immediately, so that the contents may be put back at once. Wood alcohol should of course not be used to any considerable extent. It is a dangerous substance, the fumes of which are injurious to the eyes, and often cause blindness if one is much exposed to them.

This is a good way to make use of dried apples: Cream half a cupful of butter or butter substitute with half a cupful of brown sugar; add two well-beaten eggs, three cupfuls of flour sifted with half a teaspoonful of salt, and three teaspoonfuls of baking powder; then add one cupful of stewed and sifted dried apples. Roll out on a floured baking board, cut into rounds with a biscuit cutter, and bake in a moderate oven for twenty minutes. Serve hot.

STRETCHING CURTAINS

Drying lace curtains without a stretcher may be done by laying a clean sheet on the floor or a room that is not in use, and, after the curtains are washed, stretching them on the sheet, sticking a pin through each point of lace and pinning through the sheet to the carpet; or if you have a level, sunny lawn, they may be stretched out on the grass, each point being fastened down with a wooden toothpick. When the curtains are dry it is better to pull every point or scallop off the toothpicks, leaving the latter in the ground, as in pulling the toothpicks out first the end that has been in the ground may soil the curtains.

GRAVY ON A TABLECLOTH

When gravy has been spilt by some hapless diner on your pet tablecloth rub the grease spot thoroughly with French chalk on both sides of the cloth. Fold the cloth and leave it until the next time it is needed. Lightly brush off the chalk with a soft clean brush, and your cloth will be as spotless as when freshly laundered.

FOR SCHOOL BOOKS

Provide a place for the school books and avoid having them all over the house and hard to find when the children are in a hurry to go to school. In one household shelves were put up in a back hall, each child having his own shelf. On this shelf were also placed any other articles belonging to that particular child which were picked up downstairs. A curtain was hung in front of the shelves.

IRONS WON'T STICK

Add a little lard and salt to the starch. This will give the clothes a glossy surface and it will keep the irons from sticking. Nice finish for table linen.

TO REMOVE WHITE SPOTS

The white spots which hot dishes often leave on tables and other wooden surfaces can be removed by applying a mixture composed of equal parts of alcohol, olive oil and pure cider vinegar. Shake well before using. Rub well with a woolen cloth and polish with another soft woolen cloth.

A SHOE HINT

If a boot or shoe pinches in any particular place, a cloth wrung out of very hot water and laid over the spot while the shoe is on the foot will expand the leather and remove the pinch.

FOR PRICKED FINGERS

To prevent pricked fingers when sewing, especially when quilting, protect the tpi of the fingers most used with strips of surgeon's adhesive plaster. This allows as much freedom as if the fingers were bare and one cannot prick through the plaster.

SAVE SUGAR By Using
CROWN BRAND
CORN PURE SYRUP
for all Sweetening

Sheep on Every Hill Side in New Brunswick

The New Brunswick Government through the Department of Agriculture has arranged with the Chartered Banks to help the Farmers—where assistance is needed—to buy Sheep.

The Department will not only arrange to buy Sheep **FOR** the Farmers, but will also buy good breeders **FROM** the Farmers—in other words, this branch of the Agricultural Department **WILL SUPERVISE ALL PURCHASES AND SALES OF SHEEP.**

IF A FARMER NEEDS CREDIT TO BUY SHEEP he should consult his local banker who has the necessary forms.

If you cannot buy sheep in your locality, inform the nearest banker who will notify the Agricultural Department, or, better still, notify the Department yourself and say how many Sheep you want.

KEEP YOUR EWE LAMBS

Every Ewe Lamb, weighing 80 pounds and over and of reasonable quality, should be retained by farmers for breeding purposes. Sell the males and the inferior females for butcher purposes. If you have more ewe lambs than required, induce your neighbor to purchase.

THE VALUE OF WOOL

Unwashed Wool of the best quality brought 80 cents a pound this spring, or about $5.00 a fleece.

SIXTY MILLION SHEEP

Have been lost in Europe since the war started. Wool in enormous quantities is now required to clothe the soldiers, it will take an immense quantity to reclothe the returned men in civilian dress. Prices will likely be high for ten years.

New Brunswick has the pasture, hay, roots and a climate suited to Sheep. Every farmer should consider investing in a small flock as a foundation. The first year will give approximately $4.00 worth of wool per sheep, the sheep will cost about $15.00 Is it not a good business proposition?

If you cannot purchase locally, place your order with your banker. Orders will be filled, if possible, in the order filed at this office through the banks.

For further information apply to

J. F. TWEEDDALE, Minister of Agriculture.

MONTREAL QUOTATIONS

Oats—Canadian Western, No. 3, 96; extra No. 1 feed, 93.

Flour—New standard, $10.95 to $11.05.

Bran, $35; shorts, $40; moullie, $70.

Hay—No. 2, per ton, car lots, $14.50 to $15.

Potatoes—Per bag, car lots, $1.55 to $1.60.

MONTREAL PROVISIONS

Montreal.—There was no further change in the condition of the local egg market today, but the feeling is still strong on account of the high prices prevailing at all country points and the comparatively small offerings, consequently the prospect is that prices will rule still higher in the near future.

A very firm feeling prevailed for potatoes today at the recent advance noted in prices owing to the fact that the offerings on spot continue light.

There were no important developments in the butter market today, prices for all grades being maintained with a steady trade passing which is principally for storing account for future requirements.

The trade in small cheese for domestic account was rather quiet, but prices were unchanged, with sales of 60-pound cheese and twins at 22½ to 23c per pound.

Quotations:—Cheese—Finest easterns, 22½ to 23c. Butter—Choicest creamery, 46c. Eggs—Selected, 48c; No. 1 stock, 45c; No. 2, 40c. Potatoes—Per bag, car lots, $2.25. Dressed hogs—Abattoir-killed, $28.50 to $29. Lard—Pure wool pails, 20 lbs, net, 32c to 33c.

MONTREAL MARKET FOR CATTLE ACTIVE

The receipts at the Canadian Pacific stock yards this morning for today's market amounted to 200 cattle, 200 sheep and lambs, 450 hogs and 1,000 calves. The market was active and a good demand for all lines quite cleaned up supplies. Prices were easier, and have declined about 50c per 1008 pounds at this market during the week. Choice steers were rather scarce, and most of those offered were poor quality, which made prices lower. The best sold at from $11.00 to $12.50 per 100 pounds, while inferior were as low as $10.00. Some good butcher bulls fetched $10.00 per 100 pounds, but the majority sold at from $7.00 to $9.00. Butchers' cows were in demand at from $7.50 to $10.00 per 100 pounds. The market for sheep was inactive compared with other sections of the market, and prices were from $9.00 to $12.00 per 100 pounds. Some lambs were offered, but the prices ruling for this section were exceedingly high, from $18.00 to $19.00 per 100 pounds for some choice stock, while others sold down to $11.00. Calves, of which a considerable quantity were offered, sold at from $9.00 to $15.00 per 100 pounds for good milk-fed stock. Choice select hogs sold from $19.00 to $19.25 off cars, while sows were from $2.00 to $3.00 per 100 pounds less.

CASH OATS STRONGER, ON MONTREAL MARKET

A stronger feeling prevailed in the local market for cash oats to-day, and at the close prices were marked up ½c per bushel, but the demand for supplies from all sources continues slow, and business was dull, with car lots of No. 2 Canadian western quoted at 96½c, tough No. 2 Canadian western, No. 3 Canadian western and extra No. 1 feed at 93½c, No. 1 feed at 90½c, and No. 2 feed at 87½c per bushel, ex-store.

There was no further development in the local flour situation to-day, prices for rye and barley flour being steady at the recent decline noted, with a moderate amount of business passing.

A fairly good trade continues to be

done in most lines of millfeed, there being a steady demand for supplies for domestic and country account, and the undertone to the market is steady.

The condition of the market for baled hay was unchanged, business in all directions being still dull.

Quotations:—Oats, Canadian western, No. 2, 96½c; extra No. 1 feed, 93½c. Flour, new standard grade, $10.95 to $11.05. Rolled oats, bags, 90 lbs., $5.10 to $5.15. Bran, $35. Shorts, $40. Mouillie, $67. Hay, No. 2, per ton, car lots, $14.50 to $15.

THE ADVANTAGE OF TILE DRAINAGE.

At the Experimental Station, Ste. Anne de la Pocatiere, Que., an experiment on drainage has been conducted, the results of which should be of great interest to farmers, as they teach an eloquent lesson in favor of good soil drainage, a practice which should be encouraged as much as possible in these days when maximum production is the duty of every farmer.

A certain area of level land was taken for the experiment and divided into two fields, A and B, absolutely similar in every way. Field A was underdrained by means of three-inch tile placed at a depth of four feet and thirty feet apart. Field B. was not tile drained but had perfect surface drainage. These two fields were cultivated and treated exactly alike; rotation, cultural methods, manure, choice and quality of seed, etc., being the same in each case.

Close observation has shown that larger yields were obtained on the tile drained area each year than on that which was only surface drained. The difference was rather small the year following the laying of the tile, was larger the following year and became quite marked the third year. It was most marked among crops like corn which require more warmth. In 1917 the crop of corn on the tile drained area was more than twice as great as that on the undrained field, the exact difference being 108 per cent., wheat yielding 72 per cent. more and hay 20 per cent. It might, however, be noted that the fact that the season of 1917 was exceptionally late and damp gave a special advantage to the drained area and the results might not be so marked in a normal year.

The difference in crop yields, however, is not the only point in favour of the drainage, there are other good effects also. After three years the experiment has proved that the soil on the tile drained area has become much more porous and more mellow, than the soil which was only surface drained. It can be cultivated more easily and can be worked and sown earlier in the spring. It will be readily seen that this is of great importance in sections wheer the springs are often late and the growing season relatively short. Beside this, while the soil on the undrained area dried and cracked, allowing the crops to make hardly any growth during the dry weather in July, the drained land did not show the least cracking, and the plants continued their development uninterruptedly. This difference is easily explained; the drained soil was left permeable to air and moisture, the air circulated freely and the moisture rose by capillary action without difficulty through the subsoil to the roots, while the undrained soil hardened and split, and the roots wihered for lack of air and moisture.

CARE OF MACHINERY

Even casual observers cannot fail to notice that the average Canadian farmer is very careless about housing and repairing his machinery. Students of this matter, both in the United States and Canada, estimate that by good care the average life of farm machinery could be at least doubled. On a great many farms at this time of year one may see much valuable machinery standing half covered with snow in the place where last used. The loss by this neglect is doubled, for besides the deterioration suffered by the machine there is the time taken in the spring, when time is most precious, putting the rusty machine into running order. This may result in a loss to the farm several times the value o fthe machine.

During the winter the average farmer has some leisure time and this could be most profitably employed in overhauling and repairing his machinery. Machinery should, of course, be housed and it may not be too late even now to rescue the machines from the snow drifts. Taking the machines apart effects a saving in storing space. All metal parts not painted, as on ploughs and harrows, etc., and the wearing parts of other machines should be smeared witha heavy mineral oil. All other parts should be painted after all the necessary repairs have been made and all bolts and screws tightened and replaced where necessary. Binder canvasses should be removed and hung up. The machines should be gone over one by one and left in good working condition. Worn out and broken parts may be secured more easily now than in the spring rush.

Every farm should have a machine shed with a small work shop in one end. Here the work may be carried on in inclement weather with comfort and efficiency. Such a shop will pay for itself in a few years.

Let us all do our bit and besides talking patriotism take advantage of every means possible of conserving our machinery and producing a bumper crop in 1918. J. A. S.

SOUR STOMACH

Specks Before the Eyes.

Sour stomach and biliousness are caused by a sluggish liver, for when the liver is not working properly, it holds back the bile, which is so essential to promote the movement of the bowels, and the bile gets into the blood instead of passing through the usual channel, thus causing many stomach and bowel troubles.

Floating specks before the eyes is also another indication that the liver is sluggish and requires stirring into action. This you can best do by taking Milburn's Laxa-Liver Pills. They stir up the sluggish liver, clean the coated tongue, sweeten the breath, and do away with all stomach ills.

Mr. John R. Morrison, Grand River Falls, N.S., writes: "Several months ago I was troubled with a sour stomach and had specks floating before the eyes. I took five vials of Milburn's Laxa-Liver Pills which cured, and cleared my blood before any length of time. I told my friends about it, and they got some, and they, too, find themselves different since they took them. I recommend your pills very highly."

Milburn's Laxa-Liver Pills are 25c. a vial at all dealers or mailed direct on receipt of price by The T. Milburn Co., Limited, Toronto, Ont.

SUPPLEMENTING THE INCOME

..Every farm woman tries to make the butter and egg money cover as much of her household expenses as she can. What other means for making money have you found? In this contribution, it is my hape, that I may be able to assist some one of the many farm women who are putting forth such brave efforts t oassist their husbands, and also their needy fellow beings by adding to their probably slender incime. Our farm being situated about three miles from the country village and as we have young people of our own, it has been one of our pleasures to invite some of the young people of the village, young men or women who are far from home and home pleasures, to partake of our hospitality. In so doing it has happened a few times that having enough room and to spare, we have taken a boarder. Of course in these days of runabouts and cars a young man is better able to take advantage of such a chance than one without. Such was the case here. Accordingly I had a gentleman boarder all summer and fall and it certainly was not a great deal of trouble either. I made him feel at home and that he was considered as one of the family. He took his meals with the family, sat in the kitchen or sitting room, just as he chose, often helped wash dishes, brought or carried erands from or to the village and we got along just fine. The money was very acceptable in times like 1916 when we were hailed out and we felt the extra work scarcely at all. A boarder is frequently looked upon as more bother than any gain attached, but I think it depends upon the way in which you take care of them. I did not set an extra table or fuss around, making myself more trouble and in turn making my boarder feel that he was putting me to a lot of trouble. Of course a great deal depends on your choice of boarder. I have had three boarders at different times and all very congenial and pleasant to have in your home. I always feel sorry for those who have to board in a boarding house, with no home accommodation or pleasures at all but simply from their business to their meal, from there to their room or the street or such other amusement as pool rooms and picture shows.

By this means I have added not only to our income but also to our own and our fellow beings' pleasrue.—M.M.

CREONOID

To get more milk from your cows

The cow that is free from flies always gives the biggest milk yield. To keep the cow free from these pests use Creonoid. Spray it in the stall and on the body of the animal.

Creonoid is a low-priced, powerful, non-poisonous creosote product.

Flies, lice, etc., cannot live near it.

If you have any difficulty obtaining Creonoid write to

NEW BRUNSWICK'S RESOURCES

In this material age, the cry is for "opportunity"—opportunity to develop and utilize every avaiable asset. While much interesting an dinstructive material has been published regarding the province of New Brunswick, from time to time, by both the federal and provincial governments it had chiefly to do with her possibilities from the standpoint of the agriculturist. Her vast wealth of forest and mine; her water powers and waterways; her store of fish and game were not made the subject matter of many concrete publications. It is only of comparatively recent years that the attention of the world has been effectively called to enormous protentialities of this little province by the sea.

There has been issued recently a small pamphlet of 27 pages entitled "The Province of New Brunswick, its Natural Resources, Developed and Undeveloped."

While the wealth of the forest, mine and fisheries has been dealt with in this little work it must not be supposed that the agricultural advantages of the province have been ignored. By no means. They have been given a prominent place, as they well deserve. Following them, the subjects of forestry, minerals, fisheries, water powers, water ways, angling and fur farming have been treated in a concise but intelligent manner. What adds materially to the value of the publication, is the series of maps outlining the agricultural, forestry, mineral and water power situations.

IMPORTANT POINTS IN HATCHING

During the hatching season the poultry house, and particularly the nest, should be kept clean. Clean water and a supply of whole grain should be accessible to the sitters, and a dust bath should be provided also. If more than one hatch is being taken off clean out and disinfect the nest after each hatch and put in new sod and fresh litter. Dust the hen with insect powder before putting her in the nest and again a day or two before leaving the nest with the chickens. It is a good plan to put into the dust bath a little dry sulphur or ground tobacco.

Be sure also that the house is free from mites. These little pests get into the cracks and corners of the building, and at night, as the hens are resting, they come out of their hiding place, get on the hen's body, and it does not take very many of them to make a hen so uneasy that she cannot sit. In some cases the mites become so troublesome that they actually worry the hens to death.—E. F. N.

Inspect These Bonds Before You Buy

If you think you would like to buy one or more Victory Bonds, cut out and mail us this advertisement, after first checking off amount of bond, or bonds, you would like to invest in. We will send the bonds to you at your local bank, where you may inspect them before making payment. Then, if you decide to invest you may pay for them through your local bank without extra charge or exchange on cheque.

There's no reason why anybody should keep money for which they have no immediate use drawing no interest, or drawing only 3% interest, when he or she can invest it in Victory Bonds and obtain 5½% to 5¾% interest.

And, remember, Victory Bonds are readily saleable and Free of Federal Income Tax.

You can buy Victory Bonds at the following prices;

$1,000	costs.....	$995.00
500	costs.....	497.50
100	costs.....	99.50
50	costs.....	49.75

and accrued interest.

Larger amounts $995 per $1000. Interest which is payable every six months at all banks Commences from date of your investment so write us to-day—or we will hold bonds for you to be delivered the first of the month.

NEW BRUNSWICK COMING TO THE FRONT IN SHEEP RAISING

(Continued from page 617)

gets his money at once for any loss. If the owner of the dog doing the damage is known and he fails to kill the dog he becomes liable for that damage.

"It is encouraging to find such a law as this. It is more encouraging to hear that it is being enforced.

"A lot of sentiment has been wasted by the ones who oppose cruelty to animals. The secretary of a sheep associatio had an illuminating experience. He was waited on by a committee whose members took him to task for advocating the killing of untaxed dogs.

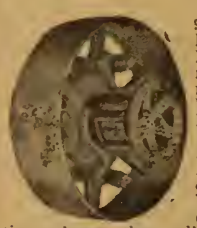
"My understanding is that you oppost cruelty to animals," he said.

"Yes."

"Well you are right about it," he said. "It is a worthy cause and I would like to join. There is one cruelty that I have long wanted to see stopped." And he got from his files of pictures, gathered from various parts of the country, photographs showing hundreds of sheep killed by dogs.

"The secretary began quoting figures as he rummaged for pictures showing the effects of rabies on human animals, but his visitors had lost interest. Rather shamefacedly they made excuses and hurried away. Thus sentiment routed sentiment.

Who chose the Friction Pulley on your Engine?



9 of the Friction Pulleys sold with Gas Engines are not manufactured by the makers of the engine. When you buy an Engine equipped with Friction Pulley you have your choice of Engine, but someone else choice of Pulley. When buying make certain of satisfaction—choose the pulley yourself—specify, or order direct. Bernard's Double Friction Pulley.

Office and Works, Fortierville, Que.

HOW TO PREVENT MOTOR ACCIDENTS

These suggestions, taken from a handbook issued jointly by a number of concerns writing automobile insurance, are based on experience gained in handling thousands of automobile accident and damage claims.

Don't drive fast with a tire that is soft or nearly worn out.

Don't permit your spot light to blind the drivers of approaching cars.

Put whatever alcohol you use in the radiator.

See that your brakes are properly set and turn your front wheels toward the curb if you leave your car on the incline.

Watch for the pedestrian who tries to cross the street ahead of you after you have received the traffic officer's signal to go ahead.

When being towed or towing another car, don't hurry; take corners slowly and look out for the pedestrians who may try to cut between the cars, not observing the tow rope.

Stop as far as possible from the travelled portion when necessary to make repairs or tire changes on the road.

If working on the road side of a car exercise extreme care.

If forced to stop at night, never permit anything or any one to stand so as to hide the tail light from the view of approaching drivers.

If you are driving, don't try to talk to persons in the tonneau.

When using an elevator, don't drive on or off before the elevator comes to a full stop at proper level.

Don't run the motor in a closed garage. The carbon monoxide in exhaust gases is odorless and colorless, yet a small percentage of it in the air is fatal.

Don't park your car, leaving headlights undimmed. But be sure to see that all lights are burning at night.

Don't allow children to drive.

Women should not be permitted to drive alone until they have become experienced operators.

Install a good non-glare device in lights, and keep your lights adjusted.

Don't park your car in the middle of the street or in the way of other drivers.

IT PAYS TO PAINT FARM MACHINERY

Would it pay to paint your farm machinery if by doing so you save 5 per cent. of the value of the machinery every year? In many cases capital is not available for the building of a tool shed but there are few farmers but who could scrape up several dollars for the purchase of sufficient paint to go over the machinery at least every three or four years. Of the various machines on the farm those constructed of wood should be painted most frequently. The manure spreader, the wooden-frame harrow and the farm wagon are some that need a good and frequent coat of paint, as they are more susceptible to weathering than iron-constructed machinery. These machines may be painted with a moderate-priced red barn paint. They should be scrubbed, rinsed and thoroughly dried before the paint is applied.

If the wood has become very open a primer should be applied first. A good method of priming is to apply heated linseed oil to the dry wood which makes a waterproof base for the coat to follow. The oil can be heated in a lard can over the shop stove. It might seem like an unpleasant task to clean up a manure spreader to paint it, but if any machinery needs it, it is the manure spreader, which is subject to the detrimental action of the manure on it causing it to rot rapidly.

It is also essential to paint iron-constructed machinery to prevent rusting. Some parts, such as planter, fertilizer cans and binder twine cans are galvanized, but in time galvanized iron will go through; it protects at its own expense, the zinc gradually disappearing as the exposure to the weather continues. The smooth-spangled surface of galvanized iron and steel parts will unfortunately tend to prevent the adherence of even the best paint and peeling may ultimately result. This condition, however, is obviated by first treating the smooth surfaces before painting with a solution of copper salts which may be prepared by dissolving 4 ounces of the chloride acetate or sulphate of copper in 1 gallon of water. By brushing on this solution the smooth surfaces are roughened, a thin deposit of copper being plated out over the surface. After an hour or so the surface may be dusted off and then painted with a prepared metal paint. Red leads and red or black oxides make good metal paints.—R. L. Sutherland.

KEEP SCREEN DOORS IN GOOD REPAIR BY PAINTING THEM

Fly time is here and the screens for the windows and doors must be gotten out of storage. In most cases this is going to reveal the sad effect of last season's neglect, and many of the screens will have to be renewed before they are used again.

Probably no other part of home equipment is so badly neglected or will return so much profit for a small amount of care as do the screens. In the first place, they should be substantially made, with corners well fitted together, fastened with screws and strengthened with flat corner irons. They should be made full length of the windows in most cases, should be hinged at top so they can be opened when desired. Each frame should be fitted carefully to its particular opening, and both opening and frame should be marked plainly so that there will be no chance for getting a frame in the wrong place. Don't depend on your memory or on a list posted some place, as you may not be there next time they are to be put in place. Metal figures made especially for this purpose can be purchased in nearly any hardware store, or very serviceable figures can be made by using the point of a screw driver.

When finished and properly fitted, the frames should be given two coats of good paint, especial care being taken to get the paint into the joints at the corners. They should then be covered with good wire screening. The copper coated wire is much better, but the cheaper black will give good service if properly cared for.

In the second place, the screens should be painted every spring before being put in place. The paint should be rather thin and should be brushed on each side of the screen, but not rubbed back and forth, as that has a tendency to produce air bubbles which will clog up the screen openings. Plenty of turpentine or other dryer should be used to make the paint dry quickly. A light coat should be given the frames, and at the same time any

Fredericton-Made Ironware Wears

Mill Supplies, Contractor's Equipment,
Pig-Troughs, Oat-Boxes, Cow-tail Holders, Etc.

The Smith Foundry Company, Ltd.
FREDERICTON, New Brunswick

screens around porches should be gone over the same way.

In the third place, all window and door screens should be taken down each fall and stored in a dry place. If possible they should be placed straight on edge in a sort of rack to keep them from twisting, although they can be laid one on top of another if carefully handled. No chaff, hay, or other trash should be allowed to collect on them.

The writer, when a boy on the home farm, made a set of full length screen frames of pieces ripped from discarded lumber, fastened them together with nails and with no irons to strengthen the corners, painted them, and tacked on ordinary black wire screening. The first three or four years these were taken down and stored each fall and painted each spring before being put up. After that they were left in place the year through, but were painted each spring. When my father left the farm 14 years later, those screens still had the original wire on them and were apparently almost as good as ever. Since that time they have been in the hands of renters and have had little attention but several of them, now 18 years old, are still on the job and in fair condition. So don't be afraid to give your screens a little paint each spring.

STARTING GAS ENGINE

Many people have difficulty in starting and operating gas engines, particularly the stationary farm engine. In many cases they fail to get their engine ready so that it can go before they begin to turn it. I very seldom have occasion to turn my stationary gas engine over more than once or twice until it starts ready for business.

Nearly all engine troubles is caused by the ignition system, which is easily understood if studied. There are just three things to make sure of: if we have the gas, a good spark, and good compression the engine must start. By this I do not mean simply that you have gas in your tank, but that you must know that it gets where the engine can use it.

For instance: If your engine is cold it may either have to be primed or the needle valve may need to be opened an extra turn, or a little dirt in the carburetor will necessitate the opening of the needle valve another turn. You must close it again after the engine starts.

Again, when the engine is hot, priming or extra opening of the needle valve will cause flooding. If these things are attended to properly and the engine fails to start promptly after three or four turns, you may as well begin to look for the trouble. Do not, however, tear the engine all to pieces the first thing, as you are not likely to have to go very deep. It is usually the little things that are responsible for most of the engine troubles and the successful engineer will attend first to all minor details, the chances being that the major troubles will not materialize.

H. C. McCORMICK.

ABSOLUTE SAFETY FROM LIGHTNING

As the season for thunder storms approaches probably most of us owning buildings will experience more or less anxiety. It is comforting to know that almost absolute safety may be provided by rodding a building. It is also interesting to know that copper rodding is no longer considered necessary for lightning protection as investigations in Great Britain and the United States have shown that iron rodding is fully as effective but, of course, not so durable. As a result of experiments the United States Government uses on some of their most important buildings three strand barbed wire. The great number of sharp points aid greatly in dissipating the charge which a building accumulates during thunder storms.

The general directions for rodding a building must emphasize several points. First the rodding must be secured directly to roof, no insulation being provided. Secondly, all the joints where wire or rods are connected together in forming a sort of cage over building, must be well made and preferably flooded with solder. Third, the whole system must be well grounded. This consists in running wires or rods from building down to the ground water level or to the water in some nearby well. In large buildings, say, over 60 and up to 100 feet long, the rodding should be grounded at every corner. In smaller buildings, grounding at two opposite corners is sufficient.

If using wire proceed as follows: Roll up 25 or 30 ft. of end of wire into a ball and bury in ground at ground water level or at least in soil which will be damp all the time. When putting back earth pour water in hole. Run wire from this ground up to corner of building, and from there up to ridge, along same to other end and down roof to corner, down to earth grounding as before. From one other corner ground as before and run wire to roof and connect at peak with first wire. Do the same at last corner. Now run wires between these at eaves and at interval of 10-20 feet run wires from ridge to eaves. If barbed wire is used no points over ridge are necessary. If plain wire or rods are used points 4 or 5 feet long must be erected at space of 15 ft. or so along ridge and over ventilators and chimneys. In a word, the object is to make a continuous network or cage over the building, nailing same to roof with staples and grounding in damp soils. J. A. STARRAK.

Macdonald College.

TURNIPS REDUCE MUTTON COST

Turnips in the ration materially reduce the cost of mutton production. A recent experiment showed that when turnips were fed at the rate of five pounds a head in connection with one pound mixed oats, bran and corn, and about two pounds clover hay, the daily cost of the ration was about 4 cents an animal. Many farmers profitably can use roots as a cheap ration, producing their mutton and wool at a material saving.

Turnips must not be overfed to sheep, nor should they be used as the bulk of the ration. They serve as a laxative and produce scouring. Owing to their watery nature turnips render the ration more palatable, and are distinctly useful when fed in moderate quantities with roughage and grain. They prevent constipation and resultant ills which so frequently occur when sheep are changed from the pasture to the sheds and put on dry feed.

Water the horses when they are cool and before giving feed.

We have noted that the man with a bee in his bonnet is quite likely to talk through his hat.

Have some of those shingles blown off the barn? Put on some new ones before more blow off. "A stitch in time saves nine."

IMPERIAL SERVICE

If you are in doubt about the proper lubricant, *ask the Imperial Oil man.* He will give you courteous attention and sound advice on your lubrication problems. That is part of Imperial Service.

LET US BE RESPONSIBLE

PUT your lubricating troubles up to the Imperial Oil man. It is his job to know the just-right oil for every lubrication need. He will recommend the oil that will end your lubrication troubles.

There is a scientifically correct lubricant for every machine requirement. For high speed motors burning gasoline, for heavy duty tractor motors or stationary motors burning kerosene, for slow-revolving, heavy shafts, for open bearings, for loose bearings, for tight bearings, you require oil that has just the right body, consistency and lubricating qualities.

There is an Imperial Oil manufactured for each particular purpose. You can get it in any part of Canada at any Imperial Oil station. There is one near you.

Imperial Oils are supplied in steel barrels and half-barrels—convenient, economical. No waste. You use every drop you pay for and know that every drop is uniform and clean.

A WAY TO SAVE SCRAPS OF FAT

Drippings and scraps of fat cut from meat that is brought into the home, may be used in a variety of ways. Savory fat made from them will be found very useful in sauteing food. Meat or potato cakes, scrambled eggs and omelets are given a very good flavor when this fat is used. A very good savory fat may be prepared in the following way:

Cut the trimmings in small pieces, or put thru a food chopper. To one pounds of unrendered or rendered fat, add a slice of onion one-half inch thick, 1 tsp. bay leaves, 1 tsp. salt and 1-8 tsp. pepper. Put all in the top of a double boiler and heat till the fat is melted. Strain thru a cloth, squeezing to remove all fat from the cracklings.

ORDER A

Sussex Little Giant Thresher

and you will be prepared to get the very best results from your Fall's Threshing

No. 1 (or 4 Horse), No. 2 (or 2 Horse), No. 3 (or one Horse) No. 5 Big Giant.

Every machine can be supplied with Tailings Elevator, Bagger Trucks, or Straw Carrier, if required. No. 1 and No. 5 can be equipped with Grain Saving Windstacker.

WE GUARANTEE SATISFACTION.

Write to-day for our catalogue, it will pay you.

THE SUSSEX MANUFACTURING CO., LTD., Sussex, N. B.

PENALTY FOR DESTROYING OR PILFERING FRUIT

Protection against the serious losses experienced in the past through rough and careless handling, wilful destruction and pilfering of fruit shipments, has been provided for in the recent revision of The Inspection and Sale Act, covered by Sec. 331 of Bill 108, which reads as follows:

"331. Every person who carelessly handles, wilfully destroys or pilfers any fruit packed in any of the packages prescribed in this Part shall be guilty of an offence and liable upon summary conviction to a penalty not exceeding twenty-five dollars."

For the information and guidance of employees, the transportation companies are arranging to post notices in express cars and at fruit shipping points, while the public will also be advised through the press and by bulletin.

Proposed Changes to Express Classification.—Application has been made to the Board of Railway Commissioners by the Express Traffic Association for approval of certain changes and additions to Section No. 22, page 11, of the Conditions of Carriage, the following probably being of some interest to fruit growers and shippers:

"(a) Each package, bundle or loose piece in a shipment must be plainly, legibly and durably marked, showing the name of only one consignee, and of only one station, town or city and province to which destined. Old marks must be removed or effaced by the shipper.

(b) Shipments wrapped in paper, or packed in boxes, crates, barrels, corrugated strawboard, pulpboard or fibreboard containers must be marked with pen, brush, stencil, waterproof crayon, or by label securely attached with glue or equally good adhesive.

(g) **Nursey Stock and Trees** in bundles or bales must be marked with not less than two tags, securely attached, and when in bales, shippers should place a duplicate address tag inside the bael for the purpose of identification.

(i) **Lot Shipments**—Except when in carloads, each package or article in a lot shipment must be marked in compliance with these requirements."

Estimated Weight Strawberry Crates.—Until an estimated weight for the 19½ x 14¼ x 6¾-24 full pint crate, satisfactory to shipper and Express Company, is decided upon, the Dominion Express Co. will accept same as actual weight, instead of the tariff estimated weight of 22 lbs., applicable last season. This will apply more particularly to British Columbia shipping.

G. E. McINTOSH,
In Charge Transportation.
Ottawa, June 24, 1918.

PLOW WHEAT FIELDS EARLY

(From U. S. Paper)

The government asks us to abstain from the use of wheat. Every loyal American is willing to sacrifice everything that is necessary to win the war. With the vast acreage in wheat in the United States, and the amount of land still available, it would seem that there should be no necessity for curtailing the consumption of wheat.

Every acre now in wheat can produce from three to five bushels more per acre next year. This extra yield would practically feed the United States, even though no more land was utilized. The solution is plowing.

Plow at the right time; and the right time to plow is just after the grain has been cut, because:

1. The ground has at that time an abundance of moisture.

2. Having the moisture, it plows easier.

3. By plowing at that time, a mulch is formed which retains the moisture and rests the land.

4. By turning the stubble under, it has time to rot and act as a fertilizer.

5. The foul weeds are killed out, and the nourishment they would consume remains in the land.

Result: From three to five more bushels per acre.

Result of not plowing at once: Each stubble will act to the ground in the same capacity as the chimney does to the stove; each one will emit the moisture which is vitally necessary, and with it go the many elements necessary to crop production.

There is no reason at this time why the plowing cannot be done immediately after the grain has been harvested. If the weather is too hot for horses to stand this hard work, then put the tractor to work. The increase in crops derived from plowing at this time will more than offset the cost of the tractor.

In the event that skilled help cannot be obtained for the operation of the tractor, then convert the automobile into a tractor. This latter can be operated by anyone who understands running the car. The feasibility of this transformation has been demonstrated so thoroughly that there is no question in regard to the benefit derived.

This is "war time" and we have got to have the food. Cereals will bring in the money with which to help carry on the enormous expense that we are now put to.

Sheep on Every Hill Side in New Brunswick

The New Brunswick Government through the Department of Agriculture has arranged with the Chartered Banks to help the Farmers—where assistance is needed—to buy Sheep.

The Department will not only arrange to buy Sheep **FOR** the Farmers, but will also buy good breeders **FROM** the Farmers—in other words, this branch of the Agricultural Department **WILL SUPERVISE ALL PURCHASES AND SALES OF SHEEP.**

IF A FARMER NEEDS CREDIT TO BUY SHEEP he should consult his local banker who has the necessary forms.

If you cannot buy sheep in your locality, inform the nearest banker who will notify the Agricultural Department, or, better still, notify the Department yourself and say how many Sheep you want.

KEEP YOUR EWE LAMBS

Every Ewe Lamb, weighing 80 pounds and over and of reasonable quality, should be retained by farmers for breeding purposes. Sell the males and the inferior females for butcher purposes. If you have more ewe lambs than required, induce your neighbor to purchase.

THE VALUE OF WOOL

Unwashed Wool of the best quality brought 80 cents a pound this spring, or about $5.00 a fleece.

SIXTY MILLION SHEEP

Have been lost in Europe since the war started. Wool in enormous quantities is now required to clothe the soldiers, it will take an immense quantity to reclothe the returned men in civilian dress. Prices will likely be high for ten years.

New Brunswick has the pasture, hay, roots and a climate suited to Sheep. Every farmer should consider investing in a small flock as a foundation. The first year will give approximately $4.00 worth of wool per sheep, the sheep will cost about $15.00 Is it not a good business proposition?

If you cannot purchase locally, place your order with your banker. Orders will be filled, if possible, in the order filed at this office through the banks.

For further information apply to **J. F. TWEEDDALE,** Minister of Agriculture.

MARITIME WOVEN WIRE FENCING

The Fencing That Does Not Bend or Break

ALL fences manufactured by the New Brunswick Wire Fence Co. Ltd. are made by the most skilled labor and of the very finest materials.

The new slide locks are outstanding features in this fence. Every other device used in this fence to prevent side slipping or up and down movement has been thoroughly tested and is guaranteed to give satisfaction.

Every yard of fencing shipped by us is thoroughly tested before leaving the factory. Our fences are not painted, but are galvanized.

We also can supply you with steel frame gates, panel fencing, etc.

Our fencing is sold by dealers in nearly every section of the Maritime Provinces. If there is no dealer in your locality write direct to

Drying---The Easiest Way to Save Food

Practical Suggestions on This Old-New Method of Saving What You Can't Can

Why You Should Dry Food for Winter

Drying is easy—a good method for the busy woman.

Drying is cheap—a good method for the economical woman.

Dried foods require little storage space.

Dried foods have lost practically nothing of nutritive value.

Why People Don't Like Dried Fruits

Because such foods are not blanched before drying, and consequently they are apt to be inferior both in flavor and color.

Because dried foods are often not soaked long enough before cooking, and so cook unevenly.

Because of poor cooking.

The food producers and food consumers of Canada are asked to conserve food. The farm homes of the Maritime Provinces are responding nobly to this call and those who are planning to take precautions that not a morsel of perishable farm grown food will be wasted, will read the following article by Helen Christine Bennett, which we reprint from the columns of the Pictorial Review for the benefit of our readers.

Whenever I begin to talk about "drying" I find that I have run against a deep-rooted prejudice. Most folks like canned goods, but they turn up their noses at anything that is "dried." It is for this reason that many of the Experiment Stations have adopted the term "dehydrating" in place of "drying." Dehydrating and drying are practically the same thing—taking out the water—only the modern system of dehydrating involves one other process which keeps the color of the vegetables and helps to retain their flavor. I am going to describe this process, but use the old term. It is shorter and less confusing and in these war times people ought to begin to discard their food prejudices.

This new system of drying, like the cold-pack system of canning, has many advantages over the old, the chief one being improvement in the color and flavor of the dried foods. In the second place, drying is easy. It is a good method for the over-busy woman or for the lazy woman or for the woman who "simply can not stand the heat." If you are any one of these, investigate the new drying.

Thirdly, drying is the method of all methods for the woman who has little space in which to store things. We are told that our enemy, Germany, stores enough nutritious stew in a small paper bag to feed a score of men and that this dried product is not only nutritious but palatable, which fact is testified to by Americans who were temporarily made prisoners at the time of the Belgian invasion and fed on paper-bag stew. A roomful of dried products means food for a regiment. The city woman who lives in an apartment with a kitchen just big enough to turn in can store a Winter's supply on a shelf. And lastly in our little sermon, it is self-evident that drying is the most economical method of food preservation.

Almost anything can be dried—beans, corn, peas, spinach, squash, cauliflower, cabbage, celery, apples, peaches, cherries, berries, tomatoes, etc. None of these things will taste "just like the fresh," or at least they do not in my experience. Neither do dried products take like canned products. And why should they? The point is that they taste good, if they are prepared in the right way.

The right way includes blanching, that is the cooking of the fruits or vegetables in boiling water for a few minutes before they are put out to dry. This, in my estimation, is even more essential in drying than in canning, and it is certainly worth while in canning. There are certain acrid odors and tastes that seem to stick to vegetables and fruits through thick and thin which only thorough blanching removes entirely. Color, which adds so much to the good "taste" of a vegetable, is much better in blanched vegetables.

To dry vegetables, clean, cut into thin strips or shreds, and drop into boiling water. Add one teaspoonful of salt to the gallon. Use a bag for this dipping as it is used in canning. When the vegetables are put in, the water naturally sinks below boiling-point. Bring it up to a boil again as quickly as possible and boil from one to five minutes. Soft, young vegetables take less time than hard, old ones. Fruits require less time than vegetables. Count one to three minutes from the time they are placed in the water, even if the water does not boil. They must not get mushy. Blanching pays well with apples, peaches, pears, apricots and quinces as it prevents them from turning dark. The only things which should not be blanched are soft berries of any kind, spinach or any greens, tomatoes, and herbs.

An Inexpensive Outfit

Drying outfits are cheap. A good many women have one like my own which consists of one clean old sheet. I happen to have a flat roof so high that it seems to be free from flies; a door gives easy access to it. On this flat roof I place my sheet and on it I put my materials ready for drying. I gather up the four corners and take the sheet in at night and put it out in the sunshine the next day. When the vegetables seem quite dry I put them into my oven in roasting-pans for a final drying off and then store them in my glass jars that are too crippled for canning.

One of the best home driers which I know is the one recommended by the New Jersey State Experiment Station. It uses the kitchen stove in this way. The ovens in most stoves have little supports on the sides for the purpose of holding the grate at various heights. To make drying trays for such an oven cut heavy galvanized window screen, one-eighth of an inch mesh, the exact size of the oven. Have your plumber bind the edges of each piece and reinforce it with strips running across. Fit the trays thus made into your oven and rest them on the grate-supports and you will have a series of oven-trays upon which thin layers of food may be placed.

This kind of drier may be used in coal, wood, as, or oil stoves; the only thing to be careful about is that the oven does not become too hot. To avoid this, **never close an oven door on drying food.** The gas or oil flame must be kept very low. In many gas ovens a pilot-light will be all the heat needed. An over-thermometer is a good thing; 130 to 160 degrees is hot enough for drying. If the oven door is shut, not only will you stand a chance of burning you food but the dried product will have an acrid taste and odor that you will not like. Give all drying things plenty of air.

The commercial driers are made of racks very similar in construction to the ones I have mentioned, only these are built into a wooden or metal frame and held thus in tiers. There are many home driers made after this model. They are intended to be hung over the kitchen stove if coal or wood is burned or to be set over a low flame on a gas or oil stove. The country woman who has her wood fire for cooking and lets it go out between meals, can economize by using one of these hanging driers over the stove morning and evening and taking it out into the sun through the day. All drying foods must be screened in some way to keep them free of flies and bugs. If you do not protect them you will have a lot of little worms developing in your dried product.

I do not know how to tell any one when dried products are really "dried"—that is, are ready to put away. I take my dried foods to the pantry and leave them in the glass jars where I can see them. If they are looked at in the early morning the glass will show any signs of moisture left in the products. If the dried products are stored in paper bags or boxes, you will have to open these and pour the contents out and air them and put them back repeating the airing process for several days.

My glass jars are a great time-saver and I am going to give them special mention because I know it is a practise in many households to throw away defective jars. If a jar has a defect that is likely to give the family broken glass to eat, throw it away by all means. But never in this day of glass shortage throw away a jar that is merely cracked or chipped a little at the mouth. In my household such a jar is washed and marked with a conspicuous label bearing a red border. Such marked jars are then placed in one corner of a shelf and from them we draw our supplies for storing rice, cereals, sugar, prunes, and a number of our dried products. We cover the jars with tops that have also proved defective. After three years of canning I have a number of these cast-offs and they are not only safer than paper boxes or bags, since they will not tear or break or let in insects, but they look so much better on my pantry shelves. I use no rubbers with these jars and I do not screw the tops tight. Other containers for dried foods may be made on the tin boxes which are bought with coffee, tea, and some biscuits. Paper bags seem to me a last resort; boxes are better. Bags are hard to keep clean on the outside and are apt to get brittle and break when products are being removed, and they always look untidy.

Beware of Insects

The glass jars enable you to watch closely for any insect life that is developing in the dried product. The appearance of any kind of worm or bug on a dried product does not mean that the product is lost, but it is a time for quick action. When a bug appears, take out the dried product, place it in a pan or on a rack, and put it in an oven at 140 degrees. Let it remain there at least two hours. Any bugs will be so dried up at the end of that time that they will be invsiible and can be washed off when the dried product is prepared. I have saved many a quart of dried beans in this way.

Dried products must be kept in a dry place or they will absorb moisture. Attics are the best places, unless you have a dry, well-ventilated pantry or

(Continued on page 668,

FLIES---Prevent Them

"Johnnie, shut that door. You'll have the house full of flies."

How often has your mother said something like that? And what did you think when she said it? Very likely you have heard that command dozens of times and thought nothing of it or, if you did think about it at all, you supposed that her chief objection to flies was that they were a nuisance. They are much more than that; they are dirty, dangerous, and a distinct source of loss to every dairyman.

Cows that spend part of their time fighting flies can't do their best work and a drop in the flow of milk is the result. Nor do the calves escape. You know very well that calves born in the late spring and early summer seldom do as well for the first few months as do those born in the winter, which simply means that it costs more to raise them and this can in part be charged up to the flies.

Another thing, where are flies most often found? Isn't it around a manure pile, an open privy vault, or any other kind of filth? Filth seems to be a fly's natural home, but the worst of it is it won't stay home. From there it may fly directly to the house and while the screen door may stop it for awhile, it gets inside sooner or later, and finds an opportunity of wiping its feet on some of the food. And that fly may actually bring some of the filth with it, too, because its body and legs are covered with hairs and bristles of different lengths.

Even worse is the possibility that that fly may carry disease. It may feed upon some filthy substance, possibly the excreta of typhoid or dysentery patients, or the discharge of some one suffering from tuberculosis. These short hairs and bristles just mentioned make a fine place to carry disease germs that may later be left on some article of human food.

Nor is that all. Asiatic cholera and infantile diarrhoea are spread in the same way and there is very strong evidence that the fly may also carry anthrax, yaws, smallpox, tropical sore, and parasitic worms so there is every reason to "swat the fly" at all times.

Naturally, the very best way to fight flies is to prevent them and in order to do this we need to know something about the way they live and multiply.

In the first place there are many different kinds of flies, among them the common house fly, the stable fly, the blue bottle fly, the green bottle fly, the little ohuse fly, the fruit fly, and a host of others. Of these our common house fly is by far the most numerous and the greatest pest. Probably 90 per cent of all the flies that got in your house last season were of that kind, so the house fly is the one for us to study.

It commonly lays its eggs upon horse manure, but it will also breed in hog manure, human excreta, and to some extent in cow and chicken manure. In fact it will lay its eggs on almost any kind of decaying vegetable or animal matter, such as rotting potatoes, ensilage, or garbage.

The number of eggs laid by a single fly is very large, probably averaging from 300 to 500. These eggs are deposited in small cracks and crevices just below the surface of the manure, where the heat from the fermentation below will keep them warm. They usually hatch in less than 24 hours and if the heat and moisture are just right it may only take about eight hours.

The maggots that come from these eggs are small, white, and nearly transparent. They feed on the manure and grow rapidly until they are about ready to pass into the pupa or sleeping stage which usually takes four or five days. Near the end of this period they get restless and usually move from their feeding ground to the edge o fthe manure pile or burrow into the soft ground nearby. Sometimes they even go quite a distance and crawl under the edges of loose material like stones, boards, etc.

The pupae or sleepers, as they are sometimes called, are almost barrel shaped and brown in color. This stage lasts only four or five days during the warm weather of midsummer but colder weather may prolong it even up to four or five months.

At the end, the adult fly emerges, works its way upward through the soil or manure, and crawls around in the air until its body hardens and its wings dry and expand. In a few days, three or four, this same fly, if a female, will begin to lay eggs and so start the whole cycle over again. So you see it only takes about twelve or fourteen days from the laying of the eggs until the young females from those eggs are ready to lay eggs themselves.

This same cycle of life continues time after time throughout the summer and accounts for the immense number of flies that we see late in the season. It is estimated that if the offspring of a single female fly were allowed to increase without checks from the middle of April to the middle of September, and if temperature and moisture conditions were most favorable, we should have 214,557,844,320,000,000,000,000 flies. Of course, this is a physical impossibility because the fly has many enemies that destroy it and conditions for its rapid increase are not always favorable. It does, however, give you an idea of what is possible and why the best and easiest way to fight flies is to prevent them.

How do flies pass the winter in our northern and central states? We seldom see one during the later winter months and yet there is no lack of them after the first few warm days of early spring. We used to think that the grown flies themselves, or some of them at least, spent the winter hiding in cracks and crevices in buildings, but this has never been proved and probably is not true. In fact, men have tried to keep flies over winter in cages inside heated buildings but none lived over 70 days.

The probability is that the fly passes the winter in the pupal or sleeping stage and emerges as an adult fly when the warm spring weather begins.

How to Fight Flies

Now, knowing something about their life history, where would you begin in an effort to prevent flies? Unquestionably the time to destroy them is before they begin to fly about and lay their eggs, which means either during the pupal or larva stage. Of these the latter is the easiest because at that time they are still at home in their breeding places.

The firs step toward this end would be to get rid of these breeding places, the manure piles and filth accumulations. Part of this can be done. More manure could be hauled directly to the field, garbage cans kept covered, and other breeding places gotten rid of. However, there is always some manure from the horses that cannot be hauled to the field daily during the summer and this is probably the largest single breeding place for flies on every farm.

Since we cannot get rid of the breeding place entirely, the next best thing is to treat it with something that will kill the fly maggots or larvae. For this purpose powdered borax will give the best results. Use about one pound of borax for every sixteen cubic feet of manure, sifting it evenly over the surface of the pile and a little heavier at the outer edges. Sprinkle water on afterwards or else dissolve the borax in water an dsprinkle the solution over the manure.

This will kill a majority of the maggots and in addition may even prevent some of the eggs from hatching. Borax does not injure the manure but it is possible that an excess of it might be injurious to growing plants, so do not use more than 15 tons of the treated manure per acre. If it is desirable to use heavier applications, powdered hellebore should be used instead of borax. Make up a solution of one-half pound of hellebore to ten gallons of water, and after allowing it to stand for 24 hours sprinkle it over the manure at the rate of 10 gallons for every 10 cubic feet of manure.

In addition to destroying as many breeding places as possible and treating the others with some chemical as recommended above, there are still other things you juniors can do to help swat the fly. Spray the cattle that are out of doors regularly with some good fly repellent. There are several on the market or, if you wish, you can mix one yourself using fish oil (1 gallon), oil of pine tar (2 ounces), oil of pennyroyal (2 ounces), and kerosene (½ pint).

Screen the windows of the house and barn and make every effort to keep the flies away frod food. Hang gunny sacks over the stable doors so that the flies are brushed off as the animals enter.

Trap and poison flies. There are small screen traps on the market that can be used in the house or you can make some yourself. Fly paper and poisons can be used, the latter with care.

The last are but helps to fight the adult flies. Remember, the most important thing is to prevent them.

Handling the Barley Crop

Some Precautions That Will Make Harvest Work Less Disagreeable

A study of the crop reports from the different grain-producing sections indicates that an enormous increase in barley acreage has been seeded this year. Not only is the amount increased in the old barley sections, but some parts of the country where the crop has not previously been grown report heavy seedings.

Several factors have brought about this crop change. Farmers have substituted barley for oats in order to help relieve the bread-flour shortage. Some have put the crop on land that had been intended for corn because the labor shortage made the cutting down of cultivated acreage necessary. In other sections of the country, where wheat normally follows corn, the corn was down so bad last fall that the wheat could not be seeded, and barley is being used to take its place.

Whatever the reason for the change, hundreds of farmers are growing barley who never before had experience with the crop. They have seeded it about as they would oats, and most of the stands which I have observed are heavy and in good thriving condition.

With the coming of harvest, special pains must be taken to keep the grain in the best condition possible. Barley ripens rapidly. It must be watched and cut when the straw first becomes yellow, or it will crinkle down badly. It should be left in the shock for about ten days, or until cured, and then, if possible, stacked or stored in barns.

Many farmers thresh from the shock, but in the case of bad weather barley discolors more quickly than either wheat or oats, and if this condition occurs, it makes a low grade of flour. Of course the crop may not be called upon heavily for human consumption. If this crop produces a billion-bushel wheat crop, most of the barley will be available for feeding purposes, but we want to handle the crop with the idea that every bushel is destined for the bread basket, and to care for the harvesting accordingly.

Another factor in connection with the reaping and threshing of barley deserves consideration. That is the point raised by so many men that the crop is disagreeable to handle. One hired man jokingly told me that the other hand would drive the binder, he would oil it and feed the horses, and the boss would do the shocking if it got done. His remark expressed the dislike which is prevalent among farmers who are not used to the crop.

Work in barley harvest is disagreeable because of the long, barbed beards which the grain carries. They break off easily, and fasten themselves in the clothing or in the flesh if driven under the skin. If not removed from the flesh they cause disagreeable festers. However, if a barley harvester is willing to take a few precautions demanded by the nature of the crop, he will find the work just as easy and agreeable as a wheat harvest. Otherwise he will probably provide himself with reasons for cussing his job.

I once harvested for six weeks in Southeastern Wisconsin, where bearded barley is the grain crop of primary importance. While there, I picked up some good, homely practical points which I was never taught in agricultural college, but which the harvesters found to be very valuable in safeguarding their physical comfort. I want to pass some of these worthwhile ideas on to those who may handle their first barley crop this season.

In the first place, on the morning harvest bgins, put on old clothes that can be thrown away when the threshing season is over. They will become so infested with prickly beards that they will be useless for future wear.

Do not wear socks. This may sound homely and senseless, but I know by experience that the beards are bound to sift into the shoes, and if socks are worn the pain sometimes becomes a torment, especially on warm days. If the feet are bare this distress is not noticeable. In case beards do break off under the skin, remove them at once. If the body becomes sore, a salt water bath will promptly relieve it.

When threshing begins the men who work round the machine should wear veils over their noses and mouths. This may sound foolish to men unacquainted with barley, but I can assure you that where the crop is regularly grown the threshers make this a constant practice. They know the discomfort caused by barley beards, and guard against it. The veil not only

keeps out the dust and chaff, but it does away with the danger of getting a beard in the mouth or nose.

I once saw a boy suffer for several days with pain caused by a barley beard which stuck in his throat while he was working on a straw pile. A veil would have prevented this.

If these precautions are observed, I am sure that no moer discomfort will arise from handling barley than from handling wheat or rye.

The country needs the barley, and the big seeding in this spring is striking evidence of the willingness of American farmers to produce the crops asked for. Whether the barley is used for human consumption or for stock feed, it is important to get the crop harvested in the best condition possible, and to do the work with the least discomfort to the laborers.

Fighting the Stomach Worm

By Dr. A. S. Alexander

More than ever before it becomes imperative to fight the stomach worm in lambs and sheep, now that every pound of wool and mutton is so sorely needed at home and abroad. Not only this, but everything possible must be done to prevent losses from other pests and diseases of sheep and the shepherd therefore must be vigilant and active if he is to succeed. The lack of help also makes the situation more difficult than usual, and for that reason it will be well to adopt the methods of management and treatment most easily followed and requiring the least assistance.

The latter consideration and the results of recent experiments make it evident that sheepmen this year should resurrect the old practice of administering sulphate of copper (bluestone) solution to lambs and sheep for the destruction of stomach worms. The gasoline treatment, so widely given, is fairly effective, but the fact that three consecuive doses are needed for the destruction of stomach worms and that some shepherds even give an extra dose 10 days later makes the treatment laborious and expensive and entails the employment of extra help. The treatment with bluestone solution, on the contrary, is quickly given in that but one dose is necessary and it would appear from experiments to me mentioned here that the worms are more surely destroyed by this drug than by gasoline.

Beginners in the sheep business probably have not heard much of the bluestone treatment, but we remember well when it was aired in the live stock and agricultural papers in the early nineties. Hutcheon of South Africa about 1891 intimated that bluestone in solution was deadly to stomach worms, but his method of administration was rather elaborate, his doses having to be graduated carefully for lambs and sheep of the different ages. This, we fancy, kept shepherds from immediately and everywhere adopting the treatment as standard, but a simpler method of treatment now has been suggested and proved effectual and should be given a thorough trial wherever stomach worms are prevalent.

The Hutcheon method published in many journals and notably in Joe Wing's little book on Sheep Farming in America, was to dissolve one pound avoirdupois of pure, finely powdered sulphate of copper (bluestone) in 2 to 4 quarts of boiling water and then add additional cold water to bring the total quantity of solution to nine and one-half gallons of water. This solution was to be given in the following doses:

Lambs 3 months old.....¾ ounce
Lambs 6 months old.....1½ ounces
Sheep 12 months old.....2½ ounces
Sheep 18 months old.....3 ounces
Sheep 24 months old.....3½ ounces

In making the solution only the purest bluestone was to be used, the amounts to be very carefully weighed and measured and the doses to be given strictly in accordance with the above table.

Stiles in America confirmed the work of Hutcheon as to the efficacy of this solution and many veterinarians and sheepmen gave it a trial, but for some reason or another the treatment did not come into general use.

Knowing that little definite and scientific work had been done to prove the degree of efficacy possessed by the different anthelmintics (worm destroyers) in common use and commonly prescribed Maurice C. Hall and Winthrop D. Foster, zoologists of the Bureau of Animal Industry, of the Department of Agriculture undertook a thorough research of the subject, trying out each anthelmintic in turn and collecting and examining all feces passed by the treated animals for several days after dosing, to recover all the worms present, then killing the animals and collecting the worms remaining.

These investigators concluded that it was unnecessary to follow the elaborate dosage plan of Hutcheon in the administration of sulphate of copper solution to sheep, so, for the sake of simplicity, they made up a 1 per cent solution of the drug and administered it in doses of 100 mils (or about 3 ounces) to adult sheep and of 50 mils to lambs under 1 year old. Three sheep so treated passed respectively 120, 240 and 314 stomach worms and showed after death the presence of 0, 49 and 3 respectively. It was found that 100 mils was somewhat too large a dose and finally 50 mils, or a little under 1½ fluid ounces, of the solution was enough for a sheep of any age.

In administering the solution a simple apparatus was used. It consisted of an overhead keg from which ran a rubber tube from a pipe let into the side near the bottom and having a nozzle attached to the free end for inserting in the mouth of the sheep or lamb. A graduated glass cylinder was placed in the course of the rubber tube and pinch controls placed upon the tube so that a correct dose might be let into the cylinder, stopped there and then allowed to flow into the sheep's mouth. Working with such an apparatus two men were able to dose at the rate of 100 sheep per hour. No bad results of any sort were experienced from thus administering an average dose of 50 mils of 1 per cent solution of sulphate of copper to the sheep treated.

A 1 per cent solution is made by dissolving 1¼ ounces of sulphate of copper in a gallon of hot water and of this the average dose is a little under 1½ ounces per animal.

The investigators found from their experiments that sulphate of copper solution earned a per centage of 93 in efficacy compared with 35 for gasoline. To this has to be credited to the copper solution the fact that but one dose did the work whereas three doses of gasoline, repeated on successive days, would b needed to obtain approximately the same results. The copper solution therefore proved for the better anthelmintic for sheep in that but one dose was needed, 1½ ounces sufficed instead of the 6 ounces of gasoline emulsion generally employed and much less labor was involved.

We hope that many readers will give the copper solution a trial this season, but let no man conclude that it will be safe to depend upon it to perfectly remove the stomach worm menace from the flock. Prevention remains much more important than medicinal treatment, no matter what drug is used. We are absolutely convinced from long observation and experience that the stomach worm, and every other internal parasite for that matter, gains the ascendency and emaciates or kills the young animal that lacks resistant power by reason of insufficient nourishing feed. In a general way it may be said that every lamb is exposed to stomach worm invasion for practically every adult sheep harbors these worms through the winter season, and with them contaminates the pasture for lambs in spring. But well fed lambs that are kept growing fast and that have inherited strong constitutions from properly fed and exercised robust sires and dams do not offer the worms their best chance for success after invasion and usually manage to withstand their presence and outlive and out-grow their weakening efferts. While this is so it nevertheless is unfortunate that any lamb should have to fight against the ill-efferts of internal parasites and for that reason every effort should be made to keep lambs growing and developing fast at the same time lessen to the utmost degree the chances of worm invasion. To that end, as every reader of this journal and of Prof. Frank Kleinheinz's admirably practical book on sheep management well knows, new grass and other green pastures should be supplied in rapid succession for the growing lamb, such rotation of pasture being as necessary for sheep as rotation is imperative to conserve fertility and insure disease-freedom for farm crops. Uncontaminated drinking water also must be supplied and the greatest possible care taken to prevent fouling of the ewe's udder with filth from old shep yards if intestinal worms are to be prevented. Eggs and embryo worms are contracted from such sources as well as from bare-bitten, sheep tainted pastures and the need of drugs and drugging will be greatly lessened by good management to avoid such dangerous features in the surroundings of sheep on the farm or ranch.

Dr. A. B. Arbuckle says:—"Any flock that is grazed from year to year on old pastures is sure to present problems that will tax the best of us.

I have used two forms of remedies with fair success, but I am convinced that an "ounce of prevention is worth a pound of cure," in this case at least. When an animal becomes badly infected, particularly a lamb, it seems practically impossible to get it back to sound health and perfect development. A lamb cannot grow normally when infected, and often becomes a sad spectacle, even though it may be saved. Therefore it is only as the last resort that I use the remedies referred to.

In recent years I have adopted the rotation plan with marked success, and, if faithfully and systematically pursued, I am sure no one need fear stomach worms. A few details must be given, as much depends upon accurate application of the plan.

First, seven pastures are required, and these must be used in definite succession. If the proper interval is not maintained the whole scheme falls through. It is, therefore, important that, under no circumstances, must sheep be allowed on any given pastures for a period of forty days, which suffices to exterminate all the larvae, except perchance a few that might be saved by finding lodgment in rabbits or other grass eating animals. Horses and cows will pick up and transmit a few. The eggs that are deposited hatch in seven or eight days and produce larvae that crawl or slide up on the grass blades, awaiting the host that must take them into the stomach for full development. If this host fails to appear in thirty days the larvae succumbs and the pasture is safe. Anyone seeing this can comprehend the plan very readily.

Second, the rotation must start about April 15th and be kept up until September, or until frost.

Third, the length of time given to each pasture is seven days. The sheep are removed to a new pasture each week.

Fourth, it is best to see that no shelter is so situated that rain can wash the droppings with the eggs to adjoining pastures.

Here is the rotation plan. It works. Last season not a single lamb showed symptoms of stomach worms, and one lamb was killed and examination revealed not one worm in stomach or intestines.

SAVING THE CALVES

One time, not so very long ago, no one bothered about the unwanted dairy calf. In the second or thrid day of his existence his career was, as a rule, ingloriously ended. Times changed. Stock values gradually went up and the poddy was no longer a burden to be killed and buried. But there were further honors awaiting him, for statesmen are now asking if his life should not be protected till he has at least reached the beef stage. Legislation of this sort is not the easiest imaginable. The state government of New South Wales has another scheme in view. They found that the Raymond Terrace factory was feeding no less than 70 calves with the refuse buttermilk and the directors were making good profit. So the government has decided that if other factories are not enterprising enough to follow suit they will establish the calf nursery themselves, just to shame the factory into the business. It's a good idea. There must be money in it for every factory, especially those which have no sale for the buttermilk. In some districts the directors put the buttermilk into pork and do well.

FINENESS OF LIMESTONE

From experiments with lime of varying fineness, conducted to determine whether the extra cost of lime finely ground is justified, the Pennsylvania Station concludes:

"On the basis of the data accumulated on the behavior of the varied sized imestone particles when incorporated in an acid soil, it may be concluded that an application of limestone in which the entire product consists of very fine material is less desirable than one consisting of varied degrees of fineness.

"The increased cost of the very finely ground limestone, together with the rapidity with which it disappears from the soil as compared with coarser materials, leads to the conclusion that an application of material all of which will pass a 10 mesh screen and include al lof the fine material incident to such grinding is sufficiently fine for soil improvement if applied somewhat in excess of the immediate need of the soil."

DEHORNING CALVES

Young calves can best be dehorned when from three to five days old, or as soon as the small buttons, which later become horns, can be felt. Clip the hair away from around them and smear a little vaseline around each button. Then moisten one end of a stick of caustic potash and rub it on the spot until the skin bleeds slightly. The vaseline protects the skin around the future horns, but care must be taken not to have too much water on the caustic potash or it will run down the head and take off the hair; or, worse yet, get in the animal's eyes. Also. always be sure to wrap a piece of paper or something around the stick to protect the hands of the operator.

THE MARITIME FARMER.

And Co-operative Dairyman
Registered Trade Mark

Semi-Monthly Journal devoted to the interests of the farmers of the Maritime Provinces.

Official Organ of The Farmers and Dairymen's Association of New Brunswick; The Nova Scotia Farmer's Association; The Nova Scotia and P. E. I Fruit Growers' Associations; The New Brunswick Fruit Growers' Association; The Maritime Stock Breeders' Association; The Maritime Bee-Keepers' Association; The New Brunswick Poultry Association, and the Newfoundland Agricultural Board.

Subscription price $1.00 per year. This paper is sent to subscribers unless a definate order for discontinuance is given.

The date after your name on the little green label on front page, is in every case the time to which your subscription is paid.

OUR GUARANTEE.—With each subscriber to the MARITIME FARMER, we positively guarantee, while bis subscription lasts, that no advertisement is allowed in our columns unless we believe that any subscriber can safely do business with the advertiser, and we agree to make good a ny loss which any sucb subscriber may sustain by trusting any such advertiser who may prove to be a deliberate swindler; but we do not undertake to adjust trifling differences between subscribers and responsibl advertisers. To take advantage of this guarantee, written come plaint must be made to the publish er within one week from the date of any unsatisfactory transact ion, with proof of the swindle and loss, and within one month from the date when the advertisement appeared, and the subscriber must prove that in writing to the advertiser be said :—"I saw" your adv. in tbe MARITIME FARMER.

CATCHING THEM YOUNG

Much may be done with a lad in pedigree stock breeding if he be caught young. The whole world seems awakened to this fact. Never has such appeal been made to the youth of the land, girls as well as boys, as in recent years in the development of the calf, pig and sheep clubs. The thought is flowering finely in this country, and the push-ahead in increased supply and improved quality can not be estimated in the calculations of economists. They have caught the idea down in Argentina, where they are not slow indeed in the utilization of methods which make directly for the expansion of stock production. The Aberdeen-Angus breeders' association of Argentina has instituted a judging contest at its annual exhibitions for boys between 15 and 20 years of age, and also for boys below 15 years, thus emphasizing the value of beginning early with the education of a boy as with the fitting of a calf. Medals and diplomas are the rewards of superior talent in these contests. The diploma, time-honored emblem of superior achievement from the Sunday schools to worlds' expositions, is in favor with the South Americans, and medals are also given. A modicum of cash is herewith suggested in addition, or in lieu of medals. Cash is wonderfully potent in directing aright the effort of the young, in encouraging endeavor, in stimulating purpose. It requires only a litttle, but that little money, paraded with pride by the lad as his very own transcends any other appeal. It is gratifying to note this recognition of youth in that stripling nation of vast possibilities and giant strides in live stock progress.

The live stock judging classes at our Maritime Fall Fairs and in past years at the Maritime Winter Fair developed some excellent judging talent among our young farmers.

PROMPT VETERINARY TREATMENT

Not long ago a farmer of the old school experimented for a couple of weeks on his sick hogs. He fed a hog tonic and various concoctions the knowledge of which he inherited from ancestral swine breeders, bnt a few more hogs got sick each day and they began to die faster and faster. He winced under the strain as hog after hog went under the sod. . He thought it might be cholera, but he did not know. Finally his wife persuaded him to call a graduate veterinarian and to agree to follow his suggestions. She thus virtually secured a promise that her husband would vaccinate his remaining hogs and stop the loss. A post mortem revealed unmistakable cholera leions and all the hogs on the place, big and little, were given the serum and virus, with the exception of a few very young litters. Over 150 head were treated and thirty of them were noticeably sick. Only seventeen of these died and all the others were saved. He paid $137 for the treatment—the value of four of the fifteen hogs that he had buried during his trial of home doctoring.

After recounting this experience and the outcome, this gray-haired man declared that the burial of $450 worth of hogs had taught him that prompt veterinary advice and treatment is the best investment a farmer can make when an animal is seriously sick and he does not know what will cure it. He regretted that he had not called the veterinarian sooner, but he thanked his lucky stars—and his wife—that he called the doctor when he did.

The high values on live stock will doubtless serve to teach many others that the money paid for needed veterinary services is well invested. The moment an owner admits to himself that he does not quite know what is wrong or what will cure an aliing animal, it is time for him to call the veterinarian. A few dollars spent for such service during the year will save a few hogs or calves, a cow or a horse. It is a better interest-paying investment than War Bonds and just as necessary for the feeding of the national army.

CULLING THE SALE BULLS

A manager of auction offerings of the beef breeds requests us to urge a more rigid culling of sale bulls. The culling should be done many months before sale time. It is an essential operation in every herd of cattle the owner of which has his face set towards improvement. Naturally sale managers delight in offerings of class and condition, as averages are generally accepted as the measure of a sale manager's ability. This gauge is not justly applied, without a consideration of the circumstances. Tail-enders are inevitable in every offering, although the tail-enders in some sales are better than the tops in others. The temptation in times of high level of values is to save all bull calves. Not many herds can follow this practice and still preserve their hard-won reputations.

The safe plan for sale managers to follow is candidly to acquaint the public with the character of the stock to be offered. When a sale report declares that the class of cattle surpassed expectations the effect is far more agreeable than when the reporter must record the presence of undesirable animals as tending to lower the average. "Scalawags" have no place in a public offering to which breeders are invited, but in times of high-priced feed mere leanness of condition must not hastily be taken for absence of intrinsic merit. Beginners usually find their first lesson in preparation for sale; sometimes it is a costly lesson. Flesh and blood contrbute mightily to satisfactory averages, even with the keenest of judges at the ringside as bidders.

Any representation before a sale that must be corrected afterwards, in the light of low prices, are sure to react disastrously. Not all offerings can be composced of top-notch animals, and it is easy enough to indicate in advertisement and catalog the exact character of the consignment, so that disappointment may not be experienced. Ample market exists for fair to good bulls; the call is strong for those which tend to wards the top in their character, while the animals which would ornament the breed best in unsered condition, and usually bring the larger degree of profit if marketed for beef, should find no place in offerings to which the general public, eager in the acquisition of breeding stocks, is invited. It is indeed desirable to cull the bull offerings at sales, even when improving the blood is in such demand as at present. However great the need, we have not yet reached that point when we should breed backward by the use of inferior sires. Sale managers will have general sympathy in their protest against the incorporation of such animals in catalogs which should have wide appeal. It is no time to try to make the tops sell the tails.

PERFORMANCE A FACTOR IN IMPROVING BREEDS

Commentors on the trend of dairy cattle breeders in Britain take note of a growing disposition to give increased attention to testing for yeilds. Probably this might more properly be called keeping milk records rather than making milk record. There is a difference. We have attained astonishing results through high-pressure methods in the test barns, and are likely to hold the position of preeminence in this regard. It is rather difficult to accept the statement that breeder sof dairy cows in Britain are too conservative or indifferent to learn by the scales and fat test the exact ability of their cows. Performance breeding has a sound basis. British breeders of meat-making animals and horses have been keen to consult the verdict of the shows in choosing sires and adopting producing strains, and it is difficult to understand why the supporters of the dairy breeds should not rest their work of betterment on a basis even more certain of results—the tested capacity of their cows. The breeding game is gamble enough. Every factor obtainable should be blended judiciously in the task of producing progeny more valuable than the generation with which breeders are working.

ENCOURAGING PURCHASES FROM THE DOMINION

Indicative of the flow of trade which is in a measure reversing its currents, the directors of the American Shorthorn Breeders' Association offer to duplicate all prides won by animals of the breed in Canada that have been bred in the United States. Ownership is not a condition. Whether the enterprise of exhibitors on this side of the line carries them into the Dominion to gain a reputation and premium reward, or whether show cattle are selected in this country and added to the herds of Canadian breeders, the offer holds. It should have an encouraging effect on trade across the line. For many years we have been liberal purchasers of cattle produced by the skill of the Canadian breeder, who has availed himself largely of rich foundation material from mother-country herds, but the tide has turned somewhat, especially with the notable upbuilding of cattle breeding in the Canadian northwest. Encouragement such as the Shorthorn association extends to buyers in the Dominion is not only of physchological influence but of somewhat more tangible character.

FARM MANURES ARE THE MOST EFFECTIVE FERTILIZER, SAYS DOMINION CHEMIST

Farm manures constitute the cheapest and most effective of all forms of fertilizers, no matter what the character of the land. For increasing soil fertility this by-product of the farm stands unequalled. It may be rightly considered as one of the most valuable assets of the farm. "The more manure the more crops, the more crops the more cattle, the more cattle the more manure." This adage tells an absolutely true story. It furnishes the explanation of the fact that mixed farming is the most rational and economical system of agriculture, the one best suited to keep up the productiveness of the soil and the one under good management most likely to give the greatest profits.

The greater part of the manure applied to the land is produced in barn stable, and piggery between autumn and spring. It is the winter's manure that the farmer mainly depends on for the corn and root crops rotation. How can this manure be handled that the best possible results may be obtained from it?

First the liquid excrement (urine) must be saved. It is far richer in nitrogen and potash, two most valable fertilizing constiuents, than the solid excrement (dung), as the following data clearly show.

Composition of Solid and Liquid Extract

	Nitrogen. p.c.	Phosphoric Acid. p.c.	Potash p.c.
Horse—			
Solid	.55	.30	.40
Liquid ...	1.35	trace	1.25
Cow—			
Solid	.40	.20	.10
Liquid ...	1.00	trace	1.35
Pig—			
Solid	.55	.50	.40
Liquid ...	.40	.10	.45
Sheep—			
Solid	.75	.50	.45
Liquid ...	1.35	.05	2.10

Thus it will be seen that weight for weight, the liquid manure, except in the case of the pig, contains much higher percentages of nitrogen and potash than solid excrment. Furthermore, these elements are in an immediately available condition for crop use, which greatly enhances their value.

Averaging results we find from 40 to 45 per cent. of the total nitrogen excreted by farm animals is in the liquid portion; in the case of the cow the proportion frequently exceeds 50 per cent.

Thousands of dollar's worth of plant food lie beneath old barns and stables in the Dominion due to leaky floors and gutters. The first step towards saving the liquid manure is to see that the floor upon which the animal rests and the guttter behind are sound and liquid tight. A concrete floor and gutter solves the porblem in the most complete and satisfactory way, but if this is not practicable at present, put the plank flooring and gutter in the best possible state of repair. Litter cannot perform its function of absorbing the liquid if the floor and gutter are faulty.

Use Sufficient Litter

The second step is to use sufficient litter or bedding to take up all free liquid.

Straw is the bedding matrial almost universally used on the farm. It will absorb from two to three times its weight of liquid. If the supply is scanty—and the past season has been a poor one for straw in many districts—it will pay to cut all the straw used as litter, for finely cut it will absorb about three times as much liquid as uncut.

Dry sawdust and fine shavings can be recommended as clean and satisfactory bedding materials. Their absorpitive capacity acccording to fineness and dryness is from two to four times that of ordinary straw.

Peat moss, commonly known as moss litter (sphagnum), makes admirable bedding; it is soft and absorbent. It will absorb about ten times its own weight of liquid and possesses the further advantage of being able to retain any ammonia that may arise from the fermentation of the manure in the stable or outside.

Muck and peat when air-dried make excellent absorbents. They are being used as such to good effect on many Canadian farms. Deposits of these materials are of no uncommon occurrence in many parts of the Dominion and their value in this connection is fairly well known. Digging and piling are all that is necessary. Their use generally is supplemental to the bedding proper, being found more especially valuable in the gutter behind the cattle, and in and about the farm buildings where there might be liquid manure or drainage to absorb. This employment of muck can be strongly advised since thereby not only may a saving of much liquid plant food be effected at little cost, but the bulk and value of the resulting manure very considerably increased by the organic matter and nitrogen of this naturally-occurring fertilizer. If there is a black muck or peat deposit on your farm or available in your neighborhood, don't neglect to use it in this way.

The Application of Manure

In so far as it may be practicable the manure should be drawn daily fresh and direct, from the barn and stable to the land. For this purpose, as long as the condition of the soil permits and there is little or no snow, use the manure spreader (into which the manure from the carrier has been directly dumped) and distribute at once. This practice means not only a great economy in labor, but the prevention of losses in plant food and humus-forming materials that inevitably follow the accumulation of manure in the yard or piling in the field. It means also an equable and uniform distribution o nthe land—a matter of no small importance.

When the snow lies deep upon the ground, still draw out the manure to the fields—daily if possible—but instead of spreading pile in small heaps of 200 to 400 pounds each. Fifty heaps of 400 pounds or one hundred heaps of 200 pounds each to the acre would mean an application of 10 tons.

With the advance of spring and the disappearance of the snow, the piles of manure, now possibly elevated a foot or more on a foundation of snow, are turned over, and when free from frost, scattered.

The adivce given in this circular as to the winter application of manure is based on the results of experimental Experimental Farm, Ottawa. These experiments proved:

1. That manure left in a loose pile in the yard suffered very considerable losses, chiefly through the leaching away of soluble nitrogen and potash compounds, but partly through fermentation (heating) and consequent destruction of organic matter with its nitrogen. In the course of a few weeks these losses may amount to one- thlrd or more of the initial value of the manure.

2. That manure in large heaps or piles—whether in yard or field—heated rapidly, even in the coldest weather. In the course of three months—January to March—manure so piled lost, chiefly through excessive fementation, 60 per cent. of its original organic matter and nearly 30 per cent. of its nitrogen.

3. That heaps of 400 pounds each, put out on the fields fresh from the barn and stable (mixed manure) showed no sign of heating throughout the experiment, January to Mrach. For the greater part of the period these small heaps were frozen through and careful analysis made immediately before scattering them in the spring showed that while frozen there had been absolutely no loss, either in plant food constitutents or organic matter. —F. T. Shutt, Dominion Chemist, Experimental Farm.

BUYING MEALS AND GRAINS FOR WINTER USE

The live stock farmer who now prepares for all necessary feeds during the coming winter and spring will save money in the initial purchase, and will be sure of ample feed sfor maintaining the productiveness and health of his animals.

The requirements of an ideal ration for any farm animals are as follows: 1. Cheapness, not necssarily per ton, but in the digestible matter contained; 2. Necessary bulk; 3. Percentage of digestible nutrients; 4. Variety; 5. Suitability to the animals and to their product; 6. Palatability; 7. Laxativeness. The experienced live stock feeder needs no explanation of any of the above points. Different classes of animals and animals of different ages require different feeds due to one or a number of the above requirements being predominant.

The cheapest and best ration for live stock must be largely home grown.

This applies to tall classes of stock, but particularly to cattle, horses and sheep. Special attention is drawn to the value and cheapness of the digestible nutrients of such rich and succulent farm grown roughages as alfalfa and clover hay, ensilage and roots.

However, the buying of mill feeds is more or less necessary on many farms and must be practised with the greatest care and skill if profits are desired.

What Feeds to Choose

In the purchasing of meals and grains to balance the farm grown roughages there are but two methods of choosing. Which of these methods the farmer uses depends altogether on the quantity and variety of farm grown feeds. If there is an abundance of well cured alfalfa or clover hay, roots and silage, then the meals purchased should be selected on the basis of total digestible nutrients but with a scarcity of rich hay and the necessity of feeding coarse grass hay straw and limited or poor quality silage then meals must be selected on the basis of digestible protein. Space prevents tabulated illustrations of these points based on feeds now found on Canadian markets. However, the following statements may be easily checked by the reader to suit his local conditions, both as to available feeds and ruling prices.

Valuing standard feeds now found on our markets at the following prices per ton, namely, corn $74; gluten feed, $60; wheat shorts, $40.40; wheat bran, $35; oats, $65; barley, $72; linseed oil meal, $65; choice cottonseed meal, $65; ground elevator screenings, $45; alfalfa hay, $20; clover hay, $18; timothy hay, $20; ensilage, $3; mangels or turnips, $4; and taking from these prices 50 to 70 per cent. of the manurial value contained, such valuation being based on pre-war fertilizer prices, the following deduction may be made. The order of cheapness for total digestible nutrients per hundred pounds in these feeds is as follows: Silage, 54c.; clover hay, $1.25; alfalfa hay, $1.31; timothy hay, $1.74; roots, $2.30; bran, $2.31; shorts, $2.40; elevator screenings, $2.91; choice cottonseed meal, $3.14; gluten feed, $3.22; oilcake, $3.39, corn, $4.02; barley, $4.24; and oats, $4.29.

On the same basis the order for the cheapness of digestible protein per hundred pounds is as follows:—Alfalfa hay, $6.41; choice cottonseed, $6.64; clover hay, $8.40; linseed oil meal, $8.77; bran, $11.27; gluten, $12.03; shorts, $12.40; elevator screenings, $19.47; roots, $21.30; timothy hay, $28.25; oats, $31.15; barley, $37.46; and corn, $45.48.

The above valuations apply particularly to the feeding of cattle. Many of the above feeds are quite unsuitable for other classes of stock and the per centage of digestibility also would vary proportionately. This, however, serves as an example of the method of selection. Special attention is drawn to the value of elevator screenings in the feeding of growing pigs and to the fact that corn at present price if available ,is slightly cheaper than barley for finishing hogs.

Only standard feeds have been mentioned, but there are many compounded meals on Canadian markets which may possibly be purchased more cheaply than many of the standard meals or grains, both as to price per ton or price per hundred pounds or digestible protein or total digestible nutrients.—E. S. Archibald, Dominion Animal Husbandman.

THE VALUE OF LITTLE REPAIRS

Too often in passing along the country roads in springtime there is to be seen the farm homestead emerging from winter snow in all to dilapidated a condition. Its forsaken, wrecked appearance gives away, somewhat, the character of the people who live there, just the class of farmer who argues that tidiness, brightness, and ornamentation do not count as so many dollars and cents. This too practical a principle in life causes many to miss much of the real happiness and contentment that is to be found in it. Nearly every farmer has a tendency to neglect those phases of farm life whose returns are not counted in so many dollars.

'A Stitch in Time Saves Nine'

The upkeep of farm buildings, seems on the surface, farm expenses, but it is really farm income, if they are always repaired immediately a damage or breakage occurs. There is the old proverb, "a stitch in time saves nine," and its practical lesson is nowhere better seen than in the timely repair around the farm. The best coworker with the stitch-in-time practice is a little forethought in winter, to place everything where it belongs. The snow has a faculty of covering up and hiding all unsavory things in its mantle of purity, but when springtime comes and lifts the veil, oh my! tin cans, old shoes, and chickens' feet decorate the home surroundings.

Every farmer who knows that wholesome surroundings make happier and more efficient lives insists that everyone about the place abandon the practice of throwing rubbish about the yard. Winter conditions hide what is going on in the way of getting rid of refuse, and spring-tide day calls for other duties. The rubbish heaps have again to be tackled and lifted anew, to be removed from sight, and it is so much time wasted that could be well conserved in anticipating what happens every time the snow leaves the landscape. That which cannot be burned in the furnace or stove should be placed in some receptacle and taken away in sleigh or wagon. The habit of having everything from smashed crockery to the anatomic remains of a faithful wheelbarrow or buggy, disfiguring the premises, should be discouraged. The accumulation of manure, rotting straw and similar refuse is a menace to health when the warm days come and become breeding places for flies and disease.

The Loose Board and Broken Window.

Dilapidated buildings not only give a farm a bad appearance, but they reduce its value to a very large extent. There is every sympathy with farmers in these days in their struggle with decreasing hired help, but there are many items of detail in looking after the farm house, barns and buildings, that do not cost much money or time, if done in time, that greatly enhances the value of the farm. A broken window, a loose board, a door hanging by one hinge, and a shingle or two off the roof, are viewed as insignificant consequence to the value or utility of the farm, but when they are allowed to remain in that condition, the destroying agency of neglect will in a few years demand a new barn for further exercise in destructive sport.

To fix these slight damages, just at the time they are first seen is a comparatively easy matter and the farmer is a richer man if he does it. Every additional fixture makes the farm

(Continued on page 668,

HORTICULTURE

PROTECTING POTATOES FROM INJURIOUS INSECTS AND FUNGOUS DISEASES

The leaves of the potato vine must be kept intact and in a thrifty condition if a maximum crop is to be obtained, and both insects and diseases should and can be fought and conquered if the well-known and thoroughly tested preventatives and remedies are used.

Spraying for the Colorado potato beetle should not be delayed until the vines are badly injured, but preparation should be made to spray as soon as the larvae or young bugs hatch. In about a week after the eggs are laid the young beetles or larvae appear and begin to devour the foliage with a rapidity which is only too well known. The last brood of larvae, which disappear into the soil before severe frost, pupate there, remaining in the ground in the form of perfect insects until the following spring. Fortunately, there are good remedies for this insect in Paris green, arsenate of lead, and other insecticides. The importance of preserving the foliage as nearly intact as possible has already been impressed on our readers. It is well known that the loss in a crop where the vines have been allowed to be devoured by potato beetles is enormous, the crop sometimes being scarcely worth digging. The longer the spraying is delayed the greater loss there will be. If cheap help can be obtained it will be advisable to spray the vines when they are quite small, or pick off the old beetles before they have deposited their eggs, but if help is scarce it may not be possible to do this, and the temptation to leave the old "bugs" alone is great, as they do little injury to the foliage. Unfortunately, on perhaps the majority of farms, nothing is done to destroy the potato beetles until the foliage is noticed partly eaten. This is too late. By the time the poiso ntakes effect the vines are badly injured and the future crop much lessened.

Potato growers should not wait until the vines are injured, but should be on the lookout for the young "bugs," and as soon as they appear an application of some good insecticide should be made. As the eggs are not all laid at the same time, the larvae do not hatch all at the same time, and it is usually necessary to spray several times before they are all killed. As it is important to kill the beetles as soon as possible, an insecticide which will act quickly is desirable, and also one that will adhere to the foliage. Paris green and arsenate of lead are two of the best poisons to use. Paris green should be applied in the proportion of 8 ounces or more Paris green to 40 gallons of water, with about 4 ounces of lime to neutralize the effect of free arsenic on the foliage. Four ounces of Paris green to 40 gallons of water will kill the insects, but does not act as quickly as eight ounces. If applied dry, a good proportion is 1 pound Paris green to 50 pounds slaked lime, land plaster or any perfectly dry powder. The dry mixture should be applied when the vines are wet, so that it will adhere better. There are strong advocates for both the wet and the dry mixtures. Wet mixtures may be put on at any time when the weather is fine, but if the best results are to be obtained dry mixtures should be applid only when the dew is on the foliage. If the dry mixtures should be applied only is moist it will adhere better than the wet mixture and will also be more evenly distributed. Arsenate of lead paste used in the proportion of two to three pounds to forty gallons of water, or powdered arsenate of lead at the rate of 1 to 1½ pounds adheres better to the foliage than Paris green, and is a good poison to use. It does not appear to kill quite so rapidly as Paris green, and a mixture is recommended of 8 ounces Paris green and 1½ pounds of paste arsenate of lead to 40 gallons of water. "Bug Death" dry and also in the proportion of 1 pound to 2 gallons of water, has been found a good insecticide, but is more expensive than Paris green.

The cucumber flea-beetle frequently does much harm to the potato crop, and being so small, is often not seen, but the results of its depredations will be found in the many small holes which may be noticed in the leaves and in the lessening of the crop on this account. Spraying with Bordeaux mixture and arsenate of lead will control this.

It is found that the parts of the leaves which are injured by the flea-beetle make suitable lodging places and points for germination of the spores of the early, and possibly, late blight. We believe that keeping vines covered with Bordeaux mixture and Paris green is the best preventative in this case.

The Early Blight or Leaf Spot Disease and the Late Blight or Rot.

Although much of the premature killing of potato vines is due to the early blight, which is frequently mistaken for the late blight, the latter is by far the more serious disease, as it spreads with much greater rapidity and in addition to the killing of the crops causes the rotting of the tubers.

The late blight usually appears between the middle of July and the first of August, though sometimes earlier or later, depending on the season and part of Canada. The strong and disagreeable odour from a potato field where the late blight is at work is familiar to all, and although it is too late to get the best results after the disease has begun to spread rapidly, it may sometimes be checked by thorough spraying at that time. The loss from blight is usually greatest from the main crop or late varieties, as the early potatoes are usually well advanced before the conditions are the most favourable for the rapid development of the disease. The weather which appears to favour the spread of the late blight, is what is usually known as "muggy," or close days with much moisture in the air. With these conditions myriads of spores germinate, and the disease spreads through the tissues of the leaves and destroys them with great rapidity. The object of spraying is to protect the leaves with the Bordeaux mixture so that if the spores germinate they are killed by it.

In a three-year experiment conducted at the Central Experimental Farm in controlling late blight there was an average difference of 94 bushels per acre of marketable potatoes in favour of the sprayed. The importance of keeping the plants growing and the tops uninjured by insects and disease was well brought out in an experiment in Vermont where it was shown that there was an increase of 119 bushels per acre during the month of September when the tops remained green and uninjured.

The cost of spraying with Bordeaux mixture is not large compared with the great average increase in yield and value of the crop from the use of it. Some years the results may not be marked but it is the average results which should be considered. A good spraying machine is important.

Formulae Recommended.

Bordeaux Mixture.—For Early and Late Blight and for Flea Beetles:—
Copper sulphate (bluestone) 4 to 6 lbs.
Unslaked lime.....4 lbs.
Water (1 barrel).....40 gallons

Dissolve the copper sulphate by suspending it in a wooden or earthen vessel containing four or more gallons of water. It will dissolve more quickly water. It will dissolve more quickly in warm water than in cold. Slake the lime in another vessel. If the lime, when slaked, is lumpy or granular, it should be strained through coarse sacking or a fine sieve. Pour the copper sulphate solution into a barrel, or it may be dissolved in this in the first place; half fill the barrel with water, add the slaked lime, fill the barrel with water and stir thoroughly. It is then ready for use. It is important not to mix the lime water and the sulphate of copper solution before diluting.

A stock solution of copper sulphate and lime wash may be prepared and kept in separate covered barrels throughout the spraying season. The quantities of copper sulphate, lime and water should be carefully noted.

IF YOU FEED YOUR TREES PROPERLY THEY'LL FEED YOU

No subject is of greater importance for the orchardist to study than maintaining the proper vigor of his trees. The successful orchardist knows, first, the desirable vigor for the tree at a given age, and second, how to fashion his pruning, tillage and intercropping to produce this desirable vigor.

There is seemingly a battle raging in plants between the nitrates and the carbohydrates—that is, between nitrogen and sugar and starch. If either one strongly prevails in the bearing tree, results are not profitable to orchardists; when they are in a balance, the results are profitable Some recent work done by Doctor E. J. Kraus, of the Oregon Experiment Station, assisted by Doctor H. R. Kraybill, recently of the agricultural chemistry department of the Pennsylvania State Collee, at the University of Chicago is interesting. This work is published as the Oregon Experiment Station Bulletin No. 149 and is entitled Vegetation and Reproduction with Special Reference to the Tomato.

Greenhouse tomatoes were used in the experiments, soils of known consistency were employed, and the plants were fed nitrogen in the form or nitrate of soda or nitrate of calcium. It was readily seen that the plants could all be grouped into three classes. First, those that were very vigorous but which had relatively few blooms and produced very few tomatoes; second, the group of plants which made desirable vegetative growth, had a large number of blooms and produced very heavily; third, the group which made very little vegetative growth, and had an enormous amount of bloom, but strangely set very few fruits.

A chemical analysis was made of these three groups and it was found that in the first group there was an excess of nitrates; that in the second group there existed a certain mathematical relation or balance, so to speak, between the nitrates on the one hand, and the carbohydrates—that is, sugar and starch—on the other hand; that in the third group a large amount of carbohydrates and a very small portion of nitrates were found.

How the Tree Works

Similar work was done by others with wheat and corresponding results were obtained. These men have shown that to get certain desirable growth and heavy fruiting, a mathematical ratio between nitrate and carbohydrate must exist. This work has great significance and seemingly a very broad application to the problems of the orchardist.

There are two distinct operations at work in the tree. Water is taken up from the roots of the trees to the leaves, which take carbon from the atmosphere and in the presence of sunlight manufacture starch and sugar, which is the basis of fruit production. The roots also furnish water, minerals and nitrogen, the great growth producers. These two—the carbohydrate manufactured by the leaves and the nitrates taken in through the roots—produce fruit and growth. If we prune back the top of the tree heavily, we reduce the supply of the stored sugar and starch and get as a substitute vigorous sappy wood, rich in nitrate but low in sugar and starch, thus pro-

ducing wood and little or no fruit.

Should we root prune, we reduce the intake of nitrates and increase the relative amount of carbohydrate and get more fruit. Root pruning, however, is more or less dangerous, and there are other ways to bring about these same results. The amount of nitrates the trees need can be influenced by tillage, irrigation, fertilizing, pruning and growing of cover crops. and so on. In a way the nitrates and carbohydrates in a tree work like the spark and feed in an automobile; nitrate is the spark of life. Too little or too much spark and not the right amount of gas means a spitting, choking, or perhaps a dead engine.

Let us see how this relation between nitrates and carbohydrates is to be applied to the trees. The first five or six years of a tree's life are the formative period. We want vigorous growth. To produce this, early and thorough tillage is very desirable. The sap that rushes up in the spring contains much raw food—that is, nitrates—and during this rapid flow of sap, before the leaves are fully expanded, the trees are making their greatest terminal growth. Later, as the leaves expand they begin the manufacture of elaborated food or sugar and starch, and the trees cease making terminal growth, the development taking the direction of increased diameter of branches and the formation of buds and spurs, the true results of the leaves' work.

By the middle of the summer the trees have made sufficient terminal growth and intensified tilalge should be discontinued, thus giving the trees an opportunity to harden for the winter and devote their energies to the manufacture of food. Early intensive tillage then encourages terminal growth, while early ceasing of tillage encourages food storage and hardening. If young trees are intercropped, hoed crops are preferable, as these require the same type of tillage as is desirable for the trees. In pruning we practice heavy cutting, as this gives us the desirable wood growth, allowing us to build a desirable framework and to force our laterals where they are needed.

By the time the trees are from six to eight years old we are looking for some financial returns. In many cases, however, we will be greatly disappointed unless we practice a number of radical changes in our orchard management, for the practices which have been so far successful with the young trees will fail to produce what we most earnestly desire—more fruit. We have by former practices built up a strong framework. If we wish now for this framework to become productive, tillage must become much less intensive(and pruning back should be discontinued for a few years, because such practices are conducive to the formation of wood rich in nitrates and will discourage the formations of elaborated food which will give us buds and spurs, the forerunners of fruit.

To get the desired development we must greatly reduce the tillage, and if the trees are extremely vigorous, perhaps discontinue the tillage for a year entirely, or even go to the extreme of growing a grain crop for a year, thus thoroughly checking the trees. This practice will not injure vigorous trees, but will generally make them produce without impairing their vitality.

After the trees come into heavy bearing everything seems to go well for a few years. The trees make a desirable wood growth and produce large crops of fine fruit, but gradually a change comes over the orchard. The fruit instead of being large, bright colored, angular, oblong and crowned, becomes round to flat, smooth and dull, though perhaps deep colored. The percentage of culls greatly increases, the trees bloom well but set poorly, the leaves become thin and yellow and very little new wood develops.

Many functional and physiological troubles appeal, such as core rot, bitter pit. apple rosette, little leaf or dieback. Why this change? The organic matter has been burned out of the soil; moisture and, above all, nitrogen are lacking. The wood of such trees probably is well supplied with sugar and starch, but the vital element, nitrogen, is found in very small quantities.

The remedy? Get nitrogen back. But how? There are many ways and every grower can surely fine one suited to his conditions. Perhaps the quickest way is to give the trees five pounds of nitrate each. If plenty of moisture is present, sow the dry crystals broadcast; if moisture is lacking, spray it on the trees, putting it into the lime-sulphur spray- -one pound of nitrate to every gallon of spray, and use five gallons of spray to the tree. Give the trees this nitrate at least a month before blossoming.

Greatly Increased Yields

With such treatment we have secured marked results on some of the light soils in our Western fruit districts. The results at times have been fairly startling. The percentage of set has increased by thirty-eight at the time of the June drop, and seventeen per cent at harvest time.

Yields, which in some cases had formerly been a bushel or less to the tree, have increased to where the trees bear from ten to even as high as twenty-ine bushels to the tree. The wood growth has been greatly stimulated, the fruit has increased in size.

In other words, the trees have changed from a devitalized, unproductive condition to a condition of normal vigor and high productivity, and become profitable commercial producers. Nitrogen, of course, may be supplied in many ways, and these same results may be secured, though probably more slowly. It would be well to supplement the use of nitrates and perhaps in some cases, if one so desired, to substitute other methods, even though they be much slower. For example, under most irrigated conditions, manures, cover crops and heavy mulching would be desirable, and under unirrigated conditions, where the moisture supply is ample, the growing of shade crops—that is, the seeding down of the orchards to more or less permanent crops, such as alfalfa, clover or vetch—would be very desirable.

In those irrigated sections where the supply of water is somewhat limited, the basin mulch system has much merit. In this system large checks are built and these are filled in with nitrogenous straws, such as alfalfa, clover, vetch and bean.

We must prune moderately but regularly. Only thus can we obtain new fruiting wood and revitalize old spurs all over the trees. Often by removing a considerable portion of the weak bearing wood we can force the food and sap into the remaining surrounding buds and spurs and greatly invigorate them. Light thinning, spread over the trees, is the type of pruning most desirable.

Some heading-in may be practiced to advantage; but moderate heading and moderate thinning are generally more desirable than extremely heavy heading or extremely heavy thinning.

We can effect and then control, to a very large extent, the vigor of our trees by the proper correlation of such various orchard practices as pruning, tillage, and fertilizing, and to be really successful and realize the best results from our orchards we must study when and how to combine these practices to bring about what we all do greatly desire—an orchard in which the trees are balanced, are producing plenty of fruit and wood and are making us mone.—C. I. Lewis in Country Gentleman.

PREPARE FOR NEXT YEAR'S SHORTAGE OF GARDEN SEEDS

While rigid selection from year to year is necessary for most kinds of vegetables when grown for seed; and while to keep them pure the different varieties have to be grown some distance apart, yet most of the seed grown in the home garden is likely to give almost or quite as satisfactory results or oven better than that which is bought, and, as some seed may be difficult to obtain next year, it is recommended for each person who has a garden to let a few plants or specimens ripen, from which seed can be saved.

It is better to mark the best plants and save the seed from them rather than to save the seed which remain after the plants have been cropped.

From experience at the Experimental Farm, Ottawa, the following minimum number of feet, plants or specimens to be saved is suggested as being sufficient to supply enough seed for the home garden in 1919; Beans, 5 ft.; corn, 1 ear; cucumbers, 1; Lettuce, 3 plants; melons, 1; peas, 5 ft.; radishes, 3 plants; spinach, 3 plants; squash, 1; tomatoes, 3.

Either reserve a few feet of the row of beans, or, better still, mark a few productive plants free from disease.

The seed stalks of lettuce are thrown up after the heads are full grown. The seed ripens rather unevenly, and, in order not to lose any of it, each head should be picked over as it shows white, it being necessary to go over the plants every few days. The plants can, however, be pulled and hung up to dry.

If some radishes are left unpulled. after being ready for use, they will soon throw up stalks, and good seed will develop. For best results the plants should be at least six inches apart.

In saving home-grown seeds, it is important to dry them as soon as possible after they are ripe, then clean them, and keep them dry until needed the foll wing spring.

Peas and beans will soon be spoiled for seed if they do not dry rapidly in the pod after being harvested.

As corn sometimes has to be pulled before it is quite hard, it is desirable to see that there is a good circulation of air around each ear. A good plan is to husk the ears and then stick each one separately on nails driven into a board and far enough apart so that the ears will not touch.

The seed of tomatoes for home use should be saved from the plant bearing the largest crop of early and best fruit. Where a quantity of seed is saved, the tomatoes may be cut in half and the pulp pressed out into some vessel, adding about one-third its volume of water. Put in a dark room until fermentation sets in, which will be in about two days, when the seed will separate readily from the pulp. Wash out and dry where the sun does not shine on it.

Following are the quantities of seed which one might expect; beans, 1 or more oz. per plant; corn, 300 to 600 kernels per ear; cucumbers, ⅛ to ¼ oz. per specimen; lettuce, ¼ oz. per plant; muskmelon, 1 to 1½ oz. per specimen; onion, ⅛ oz. per plant, pea, 4 oz. per 3 ft. or row; pepper, 1-16 to ⅛ oz. per specimen; radish, 1 oz. per plant; spinach, 1¾ oz. per plant; squash ,small seeded, 2½ oz. each; squash; large seeded, 3 oz. each; tomato, 50 to 300 each; watermelon, 2 to 3 oz. each.

DAIRYING.

EFFECT OF TUBERCULIN TEST ON MILK YIELD

Many dairymen would test their cows for their own information, if for no other reason, were they certain it would not reduce the milk flow. There need be no hesitancy. Experience shows that when the cows are tested under natural conditions the milk flow is not materially affected. When the cow is taken away from her mates, put into a hot, badly ventilated stable and tested, she usually does decrease in milk production, but it is due to the treatment and not the test.

So many fine herds have been ruined by tuberculosis that the value of the test should be emphasized. In an eastern state last winter I saw a cow stabel that contained 100 cows, but only 54 were pronounced healthy after the test. It was the same old story. A diseased cow had been brought into the herd and she had spread it to all the cows in her line, in this instance through the long water trough in front of the stalls.

A man may shut his eyes and refuse to use the test on his herd. In untested herds the disease may be spreading like wild fire and the owner blissfully unconscious of it until some day when he tries to sell an animal to go out of the state and is required to show a clean bill of health. Then he must have the animal tested. Probably it reacts. Then this man wakes up, tests his whole herd anad is chagrined to find tuberculosis all through his herd.

Every herd should be tested once a year, and some recommend semi-annual tests. It is well to know what is going on in the herd, even if the information is used solely for one's own guidance. T hetest will find the diseased cows, but a general examination will not detect tuberculosis.

In order to determine whether the tuberculin test really reduces the milk flow, we tabulated the milk produced by 10 cows before and after the test was made on the Kentucky Experiment Station herd last February. The 10 cows were giving on an average 21.45 pounds of milk daily for 3 days preceding and succeeding the tuberculin test and on the two days of test they average 20.98 pounds. There was an inappreciable decrease of 2.24 per cent. on the two days when they were tested. No one need have any fear of unfortunate effects from the test.—J. J. Hooper, Kentucky Experiment Station.

FEEDING BREEDING FEMALES

Proper feeding has much to do with issuring the full gestation period, and a normal birth of healthy, vigorous offspring. The use of good roughages, such as alfalfa aind clover hay, solves the problem excpet where trouble is caused by contagion. These facts have been fully proved by a series of experiments covering the past ten years at the Wisconsin Experiment Station, where Prof. E. B. Hart and his associates fed cows a variety of balanaced rations from calfhood to maturity and ou through several gestation periods. The first principle they discovered is that a balance between protein and energy in thefeed is not sufficient. Abundant mineral matter is necessary. Some feeds contain unknown injurious substances, whose evil effects are only counter-balanced by a suitable variety in the ration.

Even with a good roughage it was found that wheat or its by-products should not be fed continuously too liberally, or the offspring would be weak. Injurious effects were produced especially by feeding the embryo of the wheat kernel. Poor roughages, such as straw, tended to cause early delivery of offspring and failure of the cow properly to clean, with the consequent liability to starting infection. The low mineral content seemed to be the cause of injury from feeding too exclusively on straw for roughage. The experimenters significantly comment that "the condition of the straw stack herd, without reference to what the calves may be, is direct evidence of poor nutrition." Cows fed entirely on wheat products and straw, or on oat products and straw, always produced either weak or dead calves or abortions. Those fed on these rations with half of the straw replaced by alfalfa hay produced strong calves. Those fed on corn products and husked cornfodder also produced normally.

Dairymen especially should apply these teachings. While it is well known that contagious abortion is common in dairy districts, it is important for breeders to recognize the fact that it is possible to produce dead or weak premature calves from the improper selection of feeds. Contagion is doubtless blamed for much damage which it does not cause. Heavy-milking cows frequently secrete more mineral matter in thei rmilk than is supplied by their feeed. The evils of poor nutrition are added to those of contagion and the disaster is increased. On the other hand, sufficient mineral nutrition may be expected to check the damage done by infection. This phase of the problem is not covered by the Wisconsin tests but logically presents itself for thoughtful consideration, because it is known that some cows naturally possess and others acquire a degree of immunity to infection. Proper feeding may help.

THE DAIRY SITUATION IN THE UNITED STATES

Following is the text of the report and recommendations insofar as dairy products are concerned, of the advisory committee of agricultural and live stock producers, consisting of 23 members from all parts of the United States, who were in consultation in Washington for a week with the Department of Agriculture and the Food Administration:

The dairy situation in this country is such that we believe that special efforts should be made to secure a more ilberal use of milk and its products for the coming summer. The blocking up of exports of condensed milk and other dairy products caused, we understand, in part by the reduction in overseas transportation, together with the public agitation during the winter relative to the price of city milk supplies, is leading to an accumulation of stocks in excess of present demands.

It is of the utmost importance to the public welfare that there be a steady maintenance in production, and when one considers that dairying enables the maximum percentage of rough forage and feeding stuffs that have but little human food value except as used through live stock to be converted into readily available human food, it is essential that such industries be not only conserved but stimulated. If this is done, conservation must see that complete utilization of products follows.

Recommendations

We recommend, therefore, as follows:

1. The Food Administration should give the wide publicity to its present policy of recommending the liberal use of milk in order to correct any misunderstanding which still lingers in the minds of people that this food product, which is so rich in growth-promoting qualities and so essential to well-being, especially of the young, should be curtailed ii use.

3. We cordially approve the educational and demonstrational work which the Department of Agriculture is now inaugrating in the utilization of skim-milk and butter-milk as human food instead of stick feed, and believe that such work, if rapidly extended this season, will be instrumental in utilizinp large quantities of highly nutritious food products.

4. We recommend that efforts be made to secure the adopaion of such additional stable dairy products as cheese in the Army and Navy rations, as this is conentrated, highly nutritious food product, capable of transportation with the minimum use of cargo space.

Stabilized Prices for Products

5. The fundamental importance of flid milk in human nutrition makes it imperative that this essential food supply be furnished to the consumer at stabilized prices based upon the cost of production and distribution with a fair return to producer, distributor, or manufacturer. We heartily approve of the creation of the regional milk commissions established by the Food Administration to determine the cost of producing and distributing milk in its various forms, coupled with a reasonable return to the parties producing or handling the same, in the territories where controversies between the parties could not be adjusted through conferences conducted by the representatives of the various interests engaged in the milk industry and the Food Administration. We suggest that such regional bodies be established in any other territories where controversies betweeen milk producers and purchasers of milk or cream can noe be adjusted upon like principles by the Food Administration through heditation. We recommend that special consideration be given to the problems involved in the more economical methods of milk distribution as well as production, with the view that this necessary food be supplied to the public at the lowest possible price consistent with a return of cost and a reasonable profit to those engaged in the industry.

6. While we recognize that there is a general shortage of fats which may make it necessary to conserve supplies of this essential character, it is evident that there is a possibility of expanding much more readily the production of vegetable than such animal fats as dairy products. With the overseas transportation in such condition as to curtail seriously export trade, and the likelihood that thisi summer season is going to see a marked surplus in dairy products, we believe that it should be the policy of the Food Administration to recommend the wise but more liberal use of butter, cheese, condensed milk, and ice cream, with the ultimate view in mind that the supply of dairy products be maintained anad the industry not unuly suffer from overproduction and consequent demoralization this summer. By so ding the industry will be in position to meet the inevitable demand from the allies when shipping facilities become improved in the fall. When we recognize how greatly reduced the milk resources of Britain and France are, where such a large percentage of dairy animals have had to be sacrificed, it is imperative that we protect the last remaining milk reserve of the belligerent nations.

BEST TO HAVE A DAIRY COW FRESHEN AT TWO YEARS

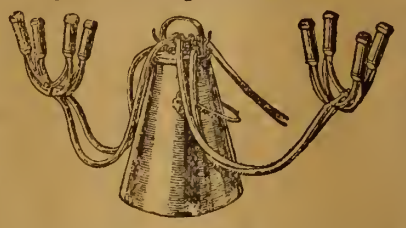
"The age at which a heifer should freshen has been a subject of great interest to me for fully a quarter of a century," said E. A. Powell, in a recent

Another Battle Won for Dairymen

FOR months we have been experimenting—investigating—testing—fighting, to find a way to make the Empire Milking Machine, already the unquestioned leader, still more efficient for the dairy farmer.

THE BATTLE IS WON.

We have given the milking machine a new heart—the pulsator is the heart of the milking machine—and the result of our experiment, the new Empire Super-Simple Pulsator, is the most wonderful development since the invention of the Empire—the competent milking machine.



To be successful a milking machine *must* have a perfectly acting pulsator to cause the alternating action of suction and massage on the teats (to imitate the calf's "suck and squeeze") to occur with absolute regularity; and to make the change from suction to massage and back again instantaneous.

The Empire Super-Simple Pulsator, the pulsator without a piston, does that and more. It really is *Super-Simple*—so simple that it can be taken apart and put together again in less than two minutes. *It has but five moving parts; nothing to wear out or "get out of gear." It cannot lose vacuum, so its action is perfect.*

It places the Empire Milking Machine immeasurably in advance of all competition. Your cows should be milked by an Empire Milking Machine with the new Super-Simple Pulsator. It will milk them more rapidly than ever—it will solve your labor problem—it will increase milk production at a decreased cost; it will transform milking from drudgery into a pleasant chore.

Our factory is overtaxed by the increased demand for Empire Milking Machines, so go to your dealer at once, see the new Super-Simple Pulsator and tell him to order your Empire outfit without delay; or write for Catalog. K

THE CANADIAN SALT CO, LIMITED

253

adress. "I have given it much thought and have arrived at the conclusion, after having carefully watched the results in hundreds of instances, that the best method is to grow the heifer well from birth, without too much flesh, but kept growing continually, have her freshen at about two years, milk her continually through, or nearly through the first year, to establish the habit of holding out, then give her a rest of two or three months with liberal feed and good care before her second freshening period.

"By this means the dairy form and milk organs are developed at a young age, when the whole system is most susceptible to the conditions of motherhood, to environment, and every influence which will have a bearing on the future development of the animal.

"By this means better dairy form, better developed milk organs are assured.

"Nearly a year in time and one calf are saved, which is no small item at the present price of milk and the value of a good calf. On the average I am confident better future cows are assured by this method.

"The coarseness and steery appearance, which is too common among heifers that are barren until three years of age, is avoided. The dairy tendency in a cow is, in a marked degree, the result of development. The young animal responds more readily to all the influences which have to do with her development than the older one. The heifer that does not breed until about three years of age is likely to develop into a coarse, steery, beefy animal, which should, if possible, be avoided. She may develop a little more size, but I do not look upon that as an advantage. The Holstein-Friesians if given a fair opportunity when are usually large enough. In fact, many of the cows of this breed are too large to be profitable and are undesirable for the average dairyman whose cows have to rustle for their living during the summer season. Extremely large cows are vry liable to become footsore and lame while grazing, especially over our hilly land, and are therefore not profitable. It is probable that a very large cow, with an abundance of feed carried to her and with water continuously at hand, consuming a large amount of feed and without any effort on her own part, may make a larger record at a much greater expense, but such a cow is not as profitable or as practicable for the ordinary farmer or dairyman. Cows that will weigh from 1,300 to 1,500 lbs. are as large as I prefer, although many of mine are of still larger size.

"By referring to the early records made by cows of the Holstein-Friesian breed, I find that nearly all the world's records, during the early introduction of the breed in this country, were made by cows which had their first calves at about two years of age. The first two-year-old tot give 13,500 lbs. of milk in a year, the first three-year-old to give 16,467lbs. milked twice a day without grain, the first four-year-old to give over 20,000 lbs., the first and only two-year-old to give 18,484 lbs., the first heifer to make 21½ lbs. butter in 7 days and 80 lbs. in 30 days, the first cow to give over 16,000 lbs. milk in a year, the first cow to give 26,000 lbs., all had their first calves from 23 to 26 months of age.

"The only entire herd of 32 two-year-olds to give an average of 12,666 lbs. as two-year-olds had their calves as juniors, and most of them at about two years of age. These instances might be multiplied indefinitely, but I am well satisfied that the method suggested above will give the largest profits and the best results, as well as the best type of dairy cows."

HOT WEATHER SUGGESTIONS ON THE CARE OF MILK

It is one of the anomalies of life that the sources of our greatest pleasures and greatest means of good may also be sources of life's greatest pains and most harm. Milk is a case in point. Milk is the best source of life's greatest need—proper and sufficient food. It may also be a cause of the destruction of life, because it may become the home or feeding ground of those death-dealing organisms which are now recognized as the cause of practically all deaths, except those due to accident or old age.

Fortunately we have discovered comparatively simple methods of combating th eeffects of what are called pathogenic (disease-producing) bacteria. These may be stated in a few short rules as follows:

1. Milk which is consumed in a raw condition must be drawn only from cows which are healthy. Milk given from cows which are sick, which are not "good-doers," and especially milk from cows with a cough, must be pasteurized.

2. As soon as the milk is drawn from the cow is should be cooled to 50 degrees F. or lower, and be kept at that temperature until consumed. This makes an unfavorable condition for the germs to grow in.

3. All pails, strainers, dippers, milk bottles, pitchers, etc., which come in contact with the milk, must be thoroughly washed and preferably steamed, or be rinsed after washing in a chloride solution, which has been found to be one of the best germicides.

4. Milk should not be exposed to the air any longer than absolutely necessary, as this seeds the milk with a fresh lot of germs. This means the keeping of milk in a closed vessel and not in an open dish.

5. "Left-over" milk from meals should not be put into the general supply, as this causes the whole lot to spoil.

6. "Left-over" milk from the sick room should be pasteurized or destroyed, as it may spread disease.

7. Milk at all times and in all places should be kept CLEAN and COOL.

DOES THUNDER SOUR MILK?

There is widespread belief that thunder sours milk for testimony is not lacking that after a severe electrical storm, milk that should have been sweet is found to have soured. It is quite natural that the souring should be attributed to the thunder, but we shall need to look elsewhere for the cause of this phenomenon. Souring is caused normally by the acidity which results from bacterial growth and sterilized milk will not sour in a thunder storm. Neither will milk that is kept on ice sour during a thunder storm. The probable explanation lies in the fact that during storms of this kind the temperature is raised sufficiently to favor the multiplication of milk-souring bacteria where the temperature is not regulated by the use of ice. W. M. F.

LISTER—The name that stands for QUALITY in Farm Machinery

LIVE STOCK.

LIVE STOCK OUTLOOK AND THE GREAT OPPORTUNITIES IT OFFERS CANADIAN FARMERS

Everywhere the question is asked: What is the outlook for the live stock farmer? The very fact that the question is so frequently asked and so much discussed is best evidence that the production of live stock is one of the most expensive and one of the most hazardous forms of farming. For example, it takes two or three years to produce and prepare an animal of the cattle kind for market. During this time it is consuming a very large amount of feed which represents a large investment in land, money and labor. In the meantime almost anything may have happened in the market and the enterprise may result in posltive loss to the farmer, even though he is producing the standard food the world must have. It is therefore perfectly natural and inevitable that the live stock farmer should look carefully about him and as far into the future as possible, especially in this time of disturbance.

It is next to impossible for us to realize that actual starvation has probably destroyed more people during this war than have been killed by bullets or died by disease, and yet such is unquestionably the fact. One-third of the population of Europe is determined to overrun the continent and ultimately the world, and it has pushed the struggle so far as to threaten not only its own existence but that of Europe as a whole. Russia is said to have drawn out of civil life no less than twenty millions of men, and in France every fifth person, including babies in arms, is now engaged in war. Clearly it is impossible to withdraw so large a proportion of our people from production and turn their lives and energies to destruction without ultimately paying the debt in reduced supplies, particularly of food.

At first thought this would seem to argue unquestionably for an unlimited increase in live stock production, but such a hasty conclusion is not warranted, because of the fact that animal food is, roughly speaking, eight to ten times as expensive as is vegetable food. That is to say, one thousand bushels of corn, for example, if consumed directly will sustain approximately ten times as many people as it could sustain if fed to animals and the animals consumed food. Of course it is true that the grass and other forage which animals eat are unsuited for human food, and yet the fact remains that in general the people can afford animal food in large quantities only when the population is scarce and land and labor are plenty. For example, China has reached a state in population where any considerable production of animal food is impossible and therefore the people must maintain themselves directly upon vegetable growth.

The time is doubtless here when America and her allies must somewhat reduce the luxury of animal food as it must reduce it luxuries of all kinds. In plain terms, we cannot afford to raise so many crops as heretofore for the feeding of animals, but must consume a larger proportion of the crops ourselves.

This all means that we must either reduce the number of our animals or reduce the expense of maintenance. As between the two it is wiser in every way to maintain numbers as far as possible, and make every saving within our power by reducing the cost of maintenance. For example, it is wiser to send our beef cattle to the markets in a less highly finished condition than it is to feed our crops to a reduced number of animals for the sake of maintaining the old-time excessive fat, most of which will not be consumed. It is wiser to somewhat reduce the production of milk by less intensive feeding methods than it is to reduce our numbers and go on feeding to the limit of consumption those mill products and other commercial feeds that are now almost cut in the middle as to amount and which have doubled in value due to disturbed market conditions.

In this connection we must remember that the great question now is not what will pay the farmer best, but what will serve us and our allies best in time of war when the nation is fighting for its life. Under these conditions the question is not how the farmer can make the most money, but how can he keep his farm at all. He knows well that if the Germans win, he will be taxed as he was never taxed before to pay the German war debt.

After the War, What?

It would be a bold prophet who would attempt to answer this question. There is no doubf but that the live stock interests of our allies across the water have suffered deproably. Neitheris there any doubt but that they will recoup themselves from herds here if we have the material to spare, and if they can find money for it spurchase. Indeed, commissions are already studying this prospect over here with a view to early importations at the close of hostilities. If the war should end soon and if we as breeders can be wise, there is no doubt in the opinion of the writer that large importations will be made by all the countries now at war, and at prices as generous as we are in honor bound to ask. If, on the other hand, a ten-year war is ahead of us, it spells exhaustion to everybody, and it might be that the nations of Europe would enter into a period of depression such as would make it impossible for them to carry out their present plans.

However, the chances would seem to be vastly in favor of tbe assumption that there will be a movement of our animals across the water even if we must arrange the credit to facilitate the transfer, and I am one who believes that the very best service which the live stock breeder today can render his country, his allies and himself, is to so manage his breeding operations as to have on hand a considerable quantity of useful breeding stock ready for sale as soon as the war is over. If this is to be done, however, the greatest care must be exercised both in the handling of the breeding problem and in the maintenance of the animals. It will not do, in the face of the present scarcity and prospective greater scarcity, to go on shovelling grain into our breeding animals without restriction as we have done in the past.

The times indicate that our breeding herds should be maintained in a less highly finished condition, and our breeders should, dufing the period of the war, cut out those classes which require a wasteage of feed for finishing. The times indicate, too, that old inferior animals should be radically eliminated, and a large herd kept in a young, growing, and prosperous condition. Such a herd can be maintained at a minimum of cost, can be quickly increased as occasion demands, and should carry no dead timber. The burden of its maintenanace is reduced to the minimum.

All these are problems which require the careful consideration of the livestock men who would best serve their country at a time like the present.

Address by E. Devenport, U. S. Food Administration, given before Wisconsin Live Stock Breeders' Association Conference.

LONG LEGS WITH MORE MEAT

In offering suggestions to a young farmer who aspires to become a breeder of bi-type hogs, a successful breeder pointed out as a fundamental characteristic the long legs of the little pigs produced by his own big sows. The man who makes his foundation selections at showring or sale from thick-fleshed mature animals may readily overlook the relation of parts which indicates probably development of growing pigs. As with calves and colts, the legs of a pig grow less than the body. If they do not have considerable length at birth a short-legged medium or small-type hog is the outcome. A big-type hog is big all over, legs included.

Big-type pigs appear longer-legged than they are. They grow so fast that they put on less fat than pigs of smaller frame. A half-inch more of fat on any pig's back and on its belly would make its legs look relatively one inch shorter. Thus the legs of the big-type pigs are both absolutely and relatively long. The breeder who picks out young animals to retain in his herd without due regard to these characteristics will fail to measure up to his expectations. Size of frame will gradually decrease.

With much justification in weights attained at an early age, big-type hogs have established their reputation for efficiency as meat-makers. Where pasture is the main dependence in summer they are accounted good grazers; where self-feeders are used from the time th little fellows first begin to eat, the big-type pigs maintain a wonderful balance of growth and simultaneous fattening. That subtle capacity for attaining greater size of frame at maturity carries with it greater meat-making possibilities. There may be no gain in economy under some circumstances but results come more quickly.

Big-type hogs have established their prestige in show and salering during the very years when medium-size hogs have been market favorites. The early-maturity of the small type fails to win favor in this practical test. The excessive size of a 900-pound boar is of no value in itself, but the giant does transmit that great digestive capacity and growing ability which bring the pigs up to 200 to 300 pounds in record time. This practical reason for the big-type hog is of overwhelming importance in these days when production must be quickened all along the line. And there is a deep-seated physiological reason for big-type efficiency. Growth is rapid when the animal is young and it becomes slower as maturity approaches. The big-type hog reaches market weight and is sold during the flush of early and rapid development.

Hogs and sheep share alike the capacity for putting on sufficient fat at an early age to meet market requirements. Not for making champion show wethers, but for producing money-making fat lambs the larger breeds of sheep have an established standing. This would be impossible if lambs would not fatten readily while growing.

The early slaughter of pigs and lambs before they are half grown may seem a sacrifice of potential meat-making powers, but consumers' specifications demand it. A reaction is evident in the sheep market. Producers are holding back spring lambs this year to make more weight and more wool on grass through the summer.

The case of cattle has been different. They do not fatten so readily when half grown. This simple fact has proved the stumbling block of hundreds of feeders every year. Any farmer can fatten a two-year-old. Only a skillful feeder can fatten a yearling. Most feeders have suffered an unfortunate experience with their first attempt to fatten calves by the time they are a year old, for the youngsters eat all the feed intended for them, but just grow and grow withou getting fat.

The war market tolerance of scanty covering over back and ribs has come to the rescue of feeders afflicted with cattle having more growth than fat. Of more importance than stopping the loss on yearlings is the bearing of this market standard on economy of making beef. With less fat demanded on the cattle it is possible to grow beef largely on roughage. Silage and hay have finished some of the most profitable cattle marketed this spring. In their ability to make meat independently of much grain consumption such cattle have become exceedingly economical producers of human food. Making beef chiefly on roughage seems to have become established for the period of the war as a sound economic policy. The cattle are marketed thinner, but their weight and finish are made largely on a growing ration. This change places cattle on a plane similar to sheep and hogs in their meat-making position and economy.

The work of cattle breeders has been guided in the past by the course of the fat cattle market. The popularity of fat yearlings was responsible for the volution of cattle of more refinement and earlier maturity than old-time feeders wanted. These smaller cattle put on fat readily at an early age. They are succeeding wonderfully well now in taking on sufficient fat with only a ration of coarse feeds. A little more time is required in finishing the cattle to meet even this lower standard, and less weight is commonly secured before the cattle are sold. The type of cattle we are breeding seems to fit very nicely into this new regime. Every energy of beef cattle breeders can for th present be bent upon increasing their herds upon pre-established lines. The feeder can readily change his methods so as to finish cattle of this type economically and suitably. Such a happy situation is

Road Debentures

Two Hundred Thousand Six Per Cent (6%) Twenty Year Road Debentures of the Province of New Brunswick Affording a Rare Opportunity for Large and Small Investors.

—O—

The Government of the Province of New Brunswick will receive applications for the purchase of any portion of $200,000.00 twenty year six per cent Road Debentures—Price Par.

These Debentures will be issued in denominations of $100.00, $500.00 and $1000.00, bearing date 15th August, 1918. The interest payable half yearly on the 15th of February and 15th August in each year. Exempt from taxation in New Brunswick, except succession duties. Principal and interest payable at any Branch of the Bank of Montreal in New Brunswick and at the Bank of Montreal in Montreal, Toronto and New York, at the option of the holders thereof.

Investors are invited to apply at once for these Debentures either by letter or wire to

of material aid in expanding the business of beef production. The proper foundation is already laid. It is now merely a matter of building upon it by the process of multiplication. E. T. R.

THE "USEFUL KIND."

Some days ago a prominent and experienced judge of high-class animals was heard to say that a group of animals was composed of the "useful kind." The insinuation was that they were rather too "plainly" bred and of "common" families, and that, though in good condition, uniform, healthy, and of proved ability as producers, it was out of the question to expect them to bring prices much above the prices they would bring on the market.

It is a matter of regret that it is deemed essential for an animal to have a pedigree that some group of supposedly expert pedigree connoisseurs see fit to commend, in order to be regarded as well-bred. It is also unfortunate that, in some cases at least, it is deemed essential that the maternal line should trace directly, though it seems to matter little how distantly, to some female which has been almost adored on account of the high favor in which some admittedly great breeder or judge has held her.

It would be consummate folly to argue that there should be no attention given to matters that deal with the bloodlines of breeding animals. Even breeders of grade animals know that this important point cannot with safety be overlooked, and the intelligent farmer who buys a brood mare or other animal is concerned about the sire and dam of the animal from which he hopes to raise good animals. But there is needed a larger appreciation of the fact that, for instance, the bloodlines of a Young Mary and of a Lavender may be almost identical, so far as actual worth, measured by heritable excellence is concerned, provided the three or more top crosses are alike. There is need for a more general appreciation of the fact that the way to breed really good animals is to give attention to the sires for a number of generations, rather than to follow in a blindly worshipful way the course mapped by the advocates of the so-called "fashionable" maternal or other bloodlines.

After all, what more can be said of an animal than that it is of a "useful kind"? Unfortunately, there is small reason to believe that this could with certainty be said of some of the dainty, highly-fitted, and successfully exhibited meat-producing animals that some new breeders have within the last few years been willing to pay large prices for. Too many beginners have started their breeding operation with highly-fitted animals that are far too costly and to delicate to be of much use in establishing a really high-class herd or flock for the economical transformation of feed into a valuable and much-needed food product.

If the agricultural colleges want to conduct a most valuable demonstration of the importance of good blood, would it not be well worth while for them to found herds of high-class, though possibly, and in fact, preferably, "plain-bred" females, mating them with animals of approved type and of breeding that would indicate that there was a strong likelihood of their being able to transmit their good qualities, regardless of the fashionableness of their breeding? Thus far it seems that more attention has been given to showyard records and fashionable breeding than to the selecting of animals that are likely to be able to reproduce well, regardless of the opportunity that they may or may not have had of making records for themselves in the showyard.

Only the other day a well-known stockman called to the writer's attention a common animal sired by a male that has been the subject of much favorable publicity. To say that the animal was far from a highly excellent one is putting it mildly indeed; but it was of the kind that one would expect from its sire. Although this sire was able to win high honors in a great show, there was never a time when he would have been regarded by capable producers of market animals as a probable sire of animals with enough natural scale and vigor and capacity to be able to make a large and profitable utilization of the feeds that must be the basis of rations used in economical production. That this animal enjoyed at least temporary fame seems more largely due to the fact that he was brought out under the management of men who were willing to provide every possible aid to development, regardless of cost, than to any extraordinary natural excellence. From toes to nose he was a tidy, well-finished animal. What he would be like in circumstances such as about all rent-paying animals must encounter seems to have been pretty well demonstrated by the appearance of his offspring, delicate, undersized, worth less than most good grades for actual use as a producer of the much needed animal products that are now high in price.

DRAFT
LOUDEN
HAY TOOLS INTO YOUR SERVICE THEY SAVE HALF THE LABOR

Louden Senior Hay Carrier
Guaranteed to handle 1500 lbs. continuously and safely. No rope trouble, no binding on track.

Louden Double Harpoon Fork
Simple and yet strong in construction. It locks when the tines are open as well as when they are closed.

Minutes mean money in haying time. In the present emergency, when labour is more difficult to obtain than ever before, Louden Hay Tools are indispensable. It makes no difference what kind of feed you handle—long timothy, dry short clover, prairie wool, fine straw, alfalfa or bound grain, a Louden Equipment will handle it to your entire satisfaction.

The Louden Senior Fork Carrier with a Giant Balance Grapple Fork or a Double Harpoon Fork, can be depended on to unload your feed quickly and easily. If your feed is long, use a Harpoon, if short and slippery a Giant Fork. For clean, quick work Louden Centre Trip Slings and Sling Carriers have always led the way. "A whole load in two lifts" shows the time you save with Louden Sling Carrier equipment.

Write for our New Illustrated Catalogue showing full line of Louden barn equipment, sent postpaid—**no charge, no obligation.**

The Louden Line includes:

Stalls and Stanchions	Hay Unloading Tools
Animal Pens of all kinds	Barn and Garage Door
Litter and Feed Carriers	Hangers
Horse Barn Equipment	Water Bowls

Overhead Carrying Systems for Factories, etc.

31_5 Martin Ave., Winnipeg, Man.
Alberta enquirers write: 1
ALBERTA DAIRY SUPPLIES Ltd., Edmonton, Alberta

The results brought about by the artistic, but not always economical, efforts of the expert fitter of animals for the show should be recognized as something else than evidence of unusual capacity or other excellence on the part of the animal that is fitted. The extra feed, prodigious in both variety and cost; the grooming and coaching; and, last but not least, the expert jockeying in the showring in order to bring out the strong points and to hide the weak ones, may win for an animal a prestige entirely out of proportion to its real worth if kept under conditions that even approximate the conditions that must be met in actual profitable production.

Let the beginner be sure to secure rather than avoid the "useful kind" in selecting foundation breeding stock, remembering that there is no other character in animals that is so permanently in style sa tuility. When the butcher inquires concerning the female line of ancestry of the animals offered or the winnings of parents that have been shown will be soon enough for the breeder to base his selections solely upon the spacious arguments of the advicates of only the limited number of families that are within the inner circle of artificial animal aristocracy. The real need of the hour is more economical animal production.

ROADSIDE.

"The essential characteristic of Shorthorns is beef, but a beef breed that can show a herd with more than 40 cows with milk records ranging from 10,000 to 13,232 lbs. is worthy of careful consideration."—B. O. Cowan.

DOMINION SHORTHORN BREEDERS' ASS'N

SHORTHORN CATTLE

The Recognized Specific of Diseases of the Horse

A sovereign remedy in powder form which cures, Coughs, Heaves, Colic, etc. It strengthens the work horse as well as the race horse, and enables them to do more and better work. It has been successfully prescribed by many veterinarians notably by Dr. J. D. Duchene, in many critical cases, where results have proved remarkable.

A 50c box will be sufficient for six days' treatment.

DR. ED. MORIN & CO., LIMITED, - - Quebec, Canada

THE HORSE

WATER EXTERNALLY AND INTERNALLY

There should always be sponges in the stable for cleaning eyes, nose, under the dock and the parts bare of hair which are tender and inconvenient to brush. In warm weather the sponge may often replace the brush with thin-haired horses to advantage. After the hair has been shed there is littlte trouble in reaching the skin surface with the sponge and in fly-time much irritation is allayed by the use of the sponge if a little coal tar dip is adder to the water. When short-coated horses sweat freely day after day there is but little dirt to be removed from the skin, yet a good deal of sticky sweat from the hair. I think I can do the work two or three times as fast with the sponge and keep the horses cleaner and the skin in better condition. I like to hose off horses when convenient in hot weather. Some people say it gives them colds. That is not my experience, but of course some horses may have no reaction after the bath and be ill-affected. Just becaause you hose a horse that is no reason why you should try to drown him or chill him to death. Three or four minutes or less will suffice to remove the sweat and make him ready for his feed, and he will be the sooner redy for work. In very hot weather wehn the water is quite warm the horse may be sprayed longer, just as his master enjoys a more protracted bath. In cool weather if the sponge is used it is not necessary t omake a horse very wet. His skin and hair will repel a considerable amount of water and he will dry almost immediately. If he does not ,throw a light blanket on him. Horses may come in prettty well cooked at noon, yet if their faces and necks are bathed off they will soon be refreshed and feed well; they appreciate it and are much comforted. There is no need to wait until a horse is overheated to resort to watercooling; it is just as useful for the well horse.

Plenty of water inside as well as outside should be a standby in hot weather. Few people realize how often a horse is exhausted merely for the want of a drink, although they know that they freuqently go for a drink themselves and cannot continue vigorous work without it. A horse or man sweating freely loses a lot of salt —often so much that some of his digestive functions are interfered with. Horses should have salt where they can help themselves freely, but if salt has been neglected care should be taken that they get enough water; otherwise when they do reach it they are very apt to hurt themselves from excess.

It has been found by actual experiments on long marches under heavy packs that salt is excreted so freely that its replacement will cause refreshment, and enable men to carry on. Not long ago a German received a jail sentence for selling so-called chicken broth lozenges that were 96 per cent salt, the rest quite guiltless of chicken but merely a composition to hold the salt together. I have myself often partaken of soup tablets, and experienced much refreshment when I knew that there was really no nutritive value to account for it, and am of the opinion that it was the saline content that proved beneficial. Horses have been kept without salt until it was apparent that they would die if the treatment were continped, and a great deal of weight is unnecessarily lost by neglecting this essential.

The lack of water is a sure cause of shrinkage. Many a horse is sacrificed to insufficient watering in the spring. He succumbs to constipation or impaction, and in summer loses weight, appetite and vigor. It may be stated that watering three or four times a day is insufficient for horses at hard work in hot weather, and that access to water throughout the night very much betters their condition. If perforce a horse must be watered only at fixed times, it is far better to tie him at the trough for at least ten minutes, and let him satisfy himself slowly. Horses soon come to know if they are expected to satisfy themselves at one or two drafts, and then be jerked away from the water. You may often see an old horse holding his mouth in the water but not drinking; he knows that by this means he can get more drink. Anyway horses like to snuffle water and wash out their noses when hot and dusty. Range horses at liberty spend several hours at water in hot weather before they leave. It is true that they are tanking up for twelve or more hours, but then they are not in hard work, sweating profusely. They sweat a good deal but so do all horrses all the time, loss of water through the skin never being arrested in warm weather. The loss is least at night; it seems that animal tissues are better refilled by evening and night watering.

Notwithstanding some risk of fighting and kicking, it usually pays better to let the big fellows run and roll at their ease, for they remain in much better condition, and much sickness is avoided as an offset to an occasional accident. Where we do not feel we can run the risk, horses should be watered after supper, and a pail of water set in the feed box for night drinking. It will practically always be found empty in the morning, and yet the horse will take about the same before breakfast.

Water should be kept clean. Lime in th etrough will precipitate the dirt and keep it sweet. Manay horses will gi short if water be foul. Water will not take the place of feed, but feed will be wasted without enough water.—L. Ogilvy.

PASTURE FOR HORSES

Whether work horses should be grazed or not depends a great deal on the abundance of the grass, and also on the age of the horses. In any event it is better that they should have enough green feed to regulate their bowels and keep them in the best condition. Many pastures simply entail a night's work after the day's labors, for so many seem never to realize the difference between what is requisite for a goose at leisure and a horse at work. Pasture with them is pasture, and it suffices. A man told me that his horses were not doing well on grass. Since I knew his pasture, I knew very well that it was not the grass that injured them, however bad they did, but a lack of roughage.

As a rule the horses themselves will furnish a good indication of whether pasture suits them or not. As a rule habit causes old horses especially to seek the barnyard after an hour or two of grazing. They seem, unless pastured throughout the years, to crave dry feed, and with but a modicum of green feed within limits, and not too rapidly, they can be restored to the grazing habit.

Of all animals horses are the most fastidious about pasture; they hate long grass as a rule, and will insist on gnawing the shorter, sweeter areas down to the roots. Often it will be found that sweetening the lower parts of the field with lime will make them graze far more evenly. The horse is naturally a dryer feeding animal than the ox. Buffalo grass just about exactly suits him; bluegrass he loves; the coarser grasses especially, if soured by rank growth, he eschews. It may sound paradoxical, but we can often have more grazing by mowing the coarse grasses, and freshening the growth. Moreover, the cured grass will also be eaten after the sun has sweetened it. A horse at the hardest work really requires dry feed, because it is more concentrated for the use of his small stomach; it requires no labor to gather and less to masticate than the great bulk of green feed that must be eaten to provide the same nutriment. It is up to us therefore to judge how much time and the energy the horse should devote to alimentation and how much he should put into travel and the collar. In any case, the changes must not be so sudden and violent that they cause stomach disturbances. In many countries with a long-grass season outside, the short-grass farm horses perform a great deal of labor, mainly on grass; they are pot-gutted, sweat profusely and are unable to endure the hours of labor at a fast pace that the dry-fed horse easily performs. Farming has to be adjusted to the team's ability. Farming in the north, with big high-fed teams, requires fewer men than elsewhere.

It is easily noted in Britain, which is grassed all over, that the further south one journeys the slower the pace of draft teams, and this is for the most part due to a greater dependence on grass. In the midland shires and to the south in the north, grazing horses is mostly coincident with the light work of midsummer; the heavy plowing and other work come in the dry feeding season. Personally, I prefer to let horses have about what green pasture they want. Continuing hay feeding without waste throughout the season the horse's appetite will lead him to consume about the right ration. Sudden change is avoided. This entails a minimum amount of grain feeding proportionate to the work to be done, the horses are at all times full, and yet not distended, and grain can be cut or increased as needed. If the pasture is good horses will fill rapidly, then rest and then fill again, which is their natural habit. So soon as full, they are apt to lie, and this rest is as important as the feed. Harassed by flies if they have to keep going all night as well as all day, they become weary. Too much stress on their legs makes them slow and lethargic. We cannot feed quite as highly as we should like but efficiency must be maintained.

In the absence of pasture some green feed should be provided in the yards, for by its use the horse gets far more out of the dry feeds furnished. This is not a matter for argument, but one that has been thoroughly tested. The one thing requisite is that the green feed be in the best condi-

PEERLESS
PERFECTION
No matter how fast it comes, the most unruly animal can't break through a *Peerless Perfection Farm Fence* — it springs back into shape.
Made of heavy Open Hearth steel galvanized wire with all the impurities taken out and all the strength and toughness left in. Every wire is crimped making the fence into one continuous spring. Top and bottom wires are extra heavy. Will not sag. Requires less posts than ordinary fence. Absolutely guaranteed.
Don't buy a rod of fencing until you get our illustrated Catalog. Describes our big line of farm, poultry and ornamental fencing. Also Peerless farm gates.
Agencies almost everywhere. Agents wanted in all unassigned territory.

Standard Hand Separator Oil

tion. I know a stable of valuable trotters that invariably get a feed of lawn grass after their Monday work-out, and another toward the end of the week, and it suits them. On the other hand, I have known horses that had to subsist on lawn grass to die of fermentation and impaction. There is nothing the matter with lawn grass for the great majority of horses, but they need other feed. Longer grasses, alfalfa, or vetches are to be preferred; the horses will not eat a great deal of it, but it will take the place of bran mashes, and millfeed is very dear. If there is no grass, crushed flax seed meal, a teaspoonful at a feed, is on the whole to be preferred to mashes at any time, and especially at present prices. Most horses will do better with their mash divided throughout the week than all at one or two feeds, but many good horsemen hold contrary opinion. L. Ogilvy.

COLLECTING THE BEST MARES

Although the draft horse business is not lively, a quiet movement is under way which is of great significance to the improvement of the breeds. The best mares are gradually drifting into the hands of the best breeders. Whenever some discouraged breeder decides to sell a high-class purebred mare, the offer is readily grasped by any of the men who are really successful breeders. Those who have made the most money produ ing pedigree horses have built their careers largely upon the best of their mares. Their success is in proportion to the character of the dams used. Even the best of sires cannot overcome the deficiencies of inferior mares. The men who are shrewd enough to seek out and buy the desirable females are also fully alive to the importance of the sire. They always havethe best that they can secure.

A period like the present, when many a breeder is getting discouraged, offers a welcome opportunity for skilled breed builders to enlarge and perfect their foundations. They can buy mares now which in times of high prices would never be for sale. With a moderate scale of values there is not such a wide spread between the best and the near-best, so it is possible now to make additions to the stud without a very heavy investment. eliminated. He is waiting for high Competition of the average breeder is prices to be in force before deciding that an increase of production is justified.

Many a desirable brood mare is raised by some man whose experience is limited. In his own hands she might never be mated to a stallion of sufficient excellence or of just the right type to intensify her merits in the offspring. Her possibilities might be lost. The improvement of a breed is really advanced by the removal of the best mares from the hands of the average breeder and their collection by men who have mastered the science of breeding draft horses. Then a desirable class of offspring is almost a certainty instead of a chance. Then further improvement is probable instead of almost impossible.—Breeders' Gazette.

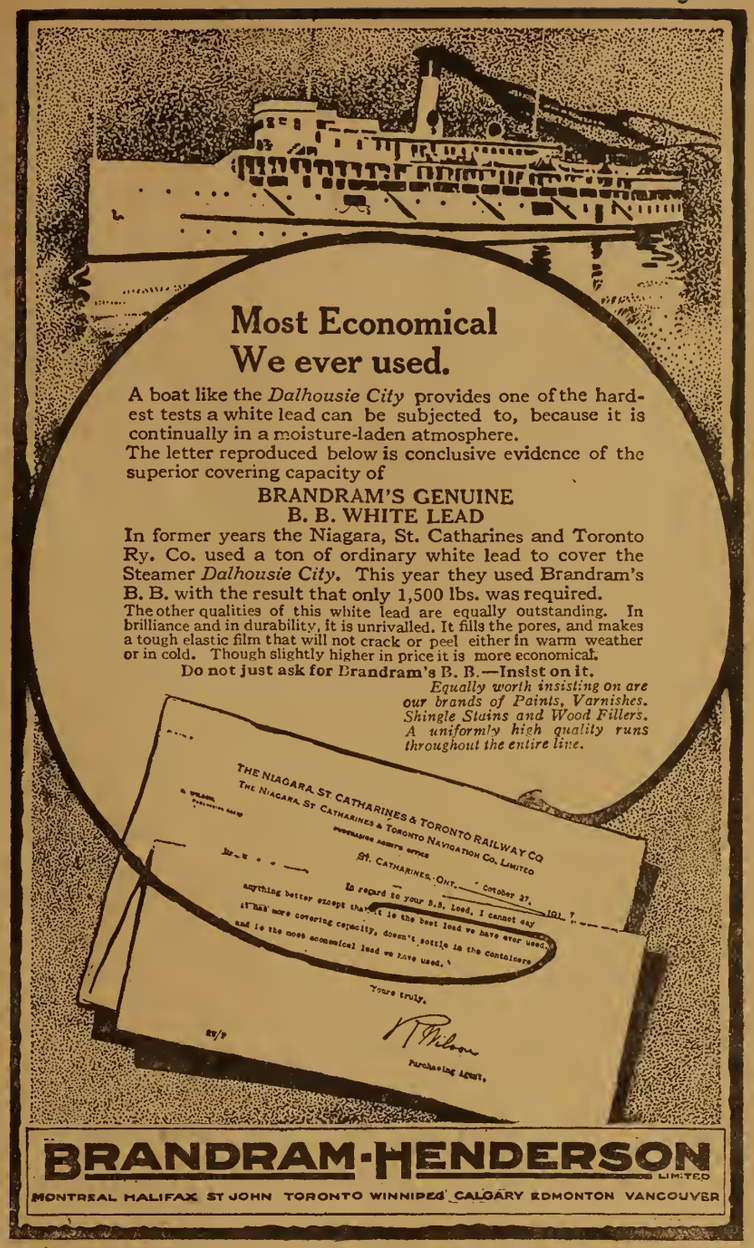
BRITAIN'S MOVE AGAINST UNSOUND SIRES

Britain will probably prohibit the traveling of stallions that are not licensed as sound. The Shire, Clydesdale and Hackney societies have approved the principle of the bill, and have suggested some amendments. Considerable opopsition is likely to develop, but the reports from buyers of horses for army use concerning the percentage of unsound animals will constitute probably the strongest backing for the bill. Its provisions will apply only to stallions that are traveled; those which stand at home will not be required to come within their scope. Such discrimination may be necessary in order to put the bill throuh, but it is certainly illogical, and would result in limited results from such drastic regulation of practices long held to be purely within the personal and private realm, free from invasion by legal enactments.

Primarily all such legislation is a distinct reflection o nthe intelligence of the farmer-breeder. It means that the farmer is too ignorant or too indifferent to breed to a sound sire. The official view of the proposed discrimination seems to be that farmers are disposed to patronize stallions which are conveniently placed at their disposal, and that if the soundness of traveling stallions is assured, it will result largely in the elimination in time of inherited equine unsoundness. Naturally such a licensed sire would command a higher service fee, and this fact may be expected to throw some mares to matings with stallions which stand at home without the approval of official inspection. It would be far better if an educational campaign could bring to horse breeders a clear and keen appreciation of hereditary unsoundnesses. No other industry has found it necessary to invoke the protection of the law against the purchase of "junk" by its members.

A man left his umbrella in the stand in a hotel, with a card bearing the following inscription attached to it: "This umbrella belongs to a man who can deal a blow of two hundred and fifty pounds weight. I shall be back in ten minutes."

On returning to seek his property he found in its place a card thus inscribed: "This card was left here by a man who can run twelve miles an hour. I shall not be back."



Most Economical
We ever used.
A boat like the Dalhousie City provides one of the hardest tests a white lead can be subjected to, because it is continually in a moisture-laden atmosphere.
The letter reproduced below is conclusive evidence of the superior covering capacity of
BRANDRAM'S GENUINE
B. B. WHITE LEAD
In former years the Niagara, St. Catharines and Toronto Ry. Co. used a ton of ordinary white lead to cover the Steamer Dalhousie City. This year they used Brandram's B. B. with the result that only 1,500 lbs. was required.
The other qualities of this white lead are equally outstanding. In brilliance and in durability, it is unrivalled. It fills the pores, and makes a tough elastic film that will not crack or peel either in warm weather or in cold. Though slightly higher in price it is more economical.
Do not just ask for Brandram's B. B.—Insist on it.
Equally worth insisting on are our brands of Paints, Varnishes, Shingle Stains and Wood Fillers. A uniformly high quality runs throughout the entire line.

A HENHOUSE BUILT FOR CONVENIENCE AND EFFICIENCY

To build a poultry house and build it to meet the requirements of the hen under constantly varying conditions, and with no protection of artificial heat for winter or natural shade for summer is a problem that must be dealt with scientifically. Ventilation is the most important fastor in the construction of all poultry houses. The body of the fowl is so constructed that it can stand neither too much cold nor too much heat. As in the dog, the body gases are mostly thrown off by respiration. Breathing is rapid, and large volumes of air rich in oxygen are necessary.

The hen, an egg machine, requires the highest type of efficient housing and general care. She is working constantly. The grinding of her feed continues at night, and throughout the day she is busily gathering more. At night she goes to roost with a full crop. Efficient lighting of her working quarters is essential for her to do her best. All parts must be equally lighted in order that the floor space allotted to each fowl may be utilized.

To construct walls for warmth in winter and coolness in summer is an absolute necessity for eggs at these times. The north, east and west walls should be built tight for winter, but for summer they must not remain so. Ventilation must be provided.

Conveniences

Convenience and arrangement of interior fixtures so as not to interfere with floor or lighting, and to be properly proportioned to the size of the flock, is another problem. Ventilation in such a house is accomplished in a way to prevent all possible drafts striking the birds. A wooden baffler is constructed in troughlike fashion. Each baffler is V-shaped, and to prevent drafts one fits over the other. All windows are on the south side. Each window consists of two sashes, both easily removed, and the upper is so constructed as to fall back into a specially made slot of triangular shape.

In this instance they are made of galvanized iron, but can easily be made of wood. Any draft that may enter the windows is then forced up next to the roof, thus preventing sudden chilling of the birds on the floor. A constant temeprature is ideal. Any appreciable variation one way or the other should be guarded against; but at the same time there must be a certain amount of circulation throughout the pen. Baffler ventliation, wth window ventilation, can meet this demand.

Each pen is fourteen feet square and accommodates fifty females and three males; is seven feet to top of plates on south side and five feet on the north. Solid wooden partitions, boarded to the roof every fourteen feet, divide the pens. Double action doors lifted to swing eight inches off he floor to clear the littter, with a removable board beneath for eleaning convenience, are used. The location of the door is best nearer the north wall than the south. This, then, at all times allows the birds the floor space on the south side, which they prefer to that of the north and which they use most.

Storage Hoppers in Each Pen

A feed house is not necessary in connection with this poultry house. Each pen contains its storage hoppers. The grain hopper is five fee tlong and fifteen to twenty inches deep, and holds approximately 500 pounds of dry mash. It is built in. All hoppers, nests and droppings boards are placed two and a half feet off the floor. This allows the fowls full use of the floor space. The water stand, grit and shell hopper are next to the window. The entire north side is taken up by the roosting space and broody coop. The droppings boards are hinged to the wall, and the supports for the perches are likewise hinged so that both may be swung up out of the way.

That does away with the chickens roosting on the perches during the daytime. The brackets supporting the boards are also hinged to swing inward and are out of the way. The opening below the boards is for ventilationand extends to a similar opening on the outside wall. Each pen has its broody coop convenient to the nests where broody hens may be quickly and easily put in jail. Trap nests are used; one is allotted to every five hens. Scantlings are done away with to support the roof. Partitions are used for this, and the trouble from hens roosting overhead is done away with.—By M. E. Dickson.

WHAT IS A HEN WORTH?

It Depends Largely Upon the Eggs She Lays

The average price of hens sold on the market varies from fifty cents to three times that amount, depending on the weight of the hen and where she is sold. But the poultry breeder should be more concerned about the value of a hen as a producer.

The difference in value of hens is to be determined by their possible product rather than by their value as market meat.

A poultry breeder paid five dollars for a standard bred hen. Sixty-three chicks were hatched from her eggs in one season. Some were poorly marked and sold on the market; others were developed and sold as breeders. The gross receipt from the products of that hen was $203.05. After deducting the cost of feed and care the owner was able to figure a net balance to the hen's credit of $154.30. The value of the hen was the amount she proved to be worth to her owner.

The value of a hen based on her production of market eggs can be accurately determined. Under normal conditions most pullets begin laying about their seventh month, and by the time they are eighteen months old they have been producing eggs one year. The cost of feeding and caring for laying hens one month has been variously estimated at from ten to twenty cents a hen, depending upon feed prices, locality and equipment.

There is another aspect of the value of a hen which constitutes the chief source of income of many standard-bred poultry plants. A hen's value during a four months' brooding season when her eggs are sold for setting, may be determined acocrding to the number of eggs laid and the price received for the eggs. The price per setting of fifteen eggs generally varies from one to twenty-five dollars a setting, depending upon quality and prize winning records of the fowls at poulrtry shows. Egg production during the brooding season may vary from three to six settings a hen and the returns may be easily estimated, depending upon the price of each setting.

Many cases coul dbe cited where hens have brought their owners fifteen or more dollars a setting for their eggs. It is therefore reasonable in such cases to credi such hens with a value equal to the returns from their eggs, less the cost of production and the expense of selling. It is easier to be assured of the value of a ten-dollar hen or even a $100 hen than it is to give any value to a hen wnich has no distinction either as a standard-bred or a layer.

Periods of Eggg Production

By a study of the annual egg records we are able to determine three distinct periods during which hens show a great variation in the number of eggs porduced. The last two months of the year and the first two months cover a period of 120 days—the winter period. The second and most favorable period for production is what is known as the brooding period, and includes the 122 days of March, April, May and June. The third period of the year in respect to egg production is made up of 123 days, consisting of the two hot months, July and August, and the two months just following, which are the molting months for a flock of poultry.

By tabulating egg records for the three periods of all the hens of four flocks it was found that during the 120 days of the winter period each hen laid an average of sixty eggs, or a fifty-five per cent. average; during the 122 days of the brooding period each hen laid ninety eggs, or a seventy-four per cent. average; and during the 123 days of the hot and molting periods each hen laid thirty-two eggs, or a twenty-six per cent. average. Thus there was an average of 182 eggs from each hen for the year. Each hen laid practically twice as many eggs the first period as she did the third and as many eggs the second period as she did during both the other periods.

By comparing the relative egg production of each hen in a flock having a low yearly record with the one given above, together with the record of a hen which laid 250 eggs in twelve months, we have what may be regarded as the comparison of the records of a low-record hen, a medium-record hen and a high-record hen.

The following observations are made from tabulated egg records for three periods of the year:

First, the low record hen laid her fewest eggs in the first period, whereas the medium and high-record hens laid their fewest eggs in the third period of the twelve months.

Second, the high-record hen showed her greatest increase over the medium-record hen in the third period.

Third, judging by the low-record hen a few eggs may be more easily produced durinfig the third period than during the first, but a larger number can be more easily produced in the first period than in the third, judging by the medium and high record hens.

Fourth, the variation between the number of eggs laid by the low-record hen during the three periods is greater than that shown between the results of the three periods by the high-record hen, indicating that the possible maximum average for the year approaches the maximum average for the highest period with the heaviest layers.

Causes of Low Egg Yields

Aside from the natural tendencies of a hen toward laying, any of the following causes may prevent the highest record in egg production:

Failure to provide a full balanced ration, at all times; fresh water, grit, shell, ash and dusting at all times; extreme changes of weather, cold, heat or wet; contracting mild or extreme forms of diesease; broodiness, lice and mites, irregular times of feeding, accumulated filth, overcrowding, lack of exercise, old and foul earth in runs, drafts, molting process, lack of ventilation, lack of growing vegetation, changing of hens from one pen to another, scaring or irritating hens, becoming too fat.

Most of the hindrances to egg production may be avoided by constant care and attention. In the order of their persistence they are: Molting, broodiness, heat, cold lice an mites, mild forms of disease and fattiness.

Any of these is apt to prevent the highest possible egg production in the flocks of the most skilful and best-equipped poultry raisers.

Mild forms of disease are very common among fowls during the third and first periods of the laying year. In the second period of the year succulent vegetation generally cleans and regulates the digestive tract sufficiently to keep down any form of disease.

The color and texture of the comb and wattles, together with the color, and condition of the droppings of a fowl, indicate the health. Certain types of bowel trouble are exceedingly prevalent among laying hens and hinder egg production, depending on the degree of severity. Too much fat is due to overfeeding of fat-forming feed and invariably develops about the egg organs of some hens during the hot months.

It is a well-known fact among poultry breeders that the extremes of weather and the sudden variations in temperature affect very noticeably the yearly egg records; however, neither cold nor heat as hindrances fully accounts for low averages in the winter and hot periods.

As a rule, low averages are the result of combined conditions which are partly due to weather, the kind of care hens receive, and the egg-laying ability of the individual hens.

SELECTING LAYING HENS

"Is there any way by measuring that one may tell how many eggs a hen will lay? Will a hen transmit her

form to her progeny? Is there any rule as to the color of the pellets on the head as to whether a hen is a layer or not? Will a laying hen's eggs turn to white from yellow is she is a heavy layer? If a hen drop down behind will she be profitable to keep as a layer?—H. N. S.

Reply by Miller Purvis.—I have three systems by which it is alleged, the laying abiliay of a hen can be determined, the three costing at the originators' prices $11. One of them I bought about fifteen years ago, and the others later. All of them pretend to teach a method by which observation of the position of the pelvic bones will enable any one to determine beforehand about how many eggs a hen will lay in a year. These systems are of value only while a hen is laying, and then only to tell whether she is laying. They have been thoroughly tested but have failed in so many instances that they are not considered of great value. All these systems are all copyrighted I can not go into details here. The originator of one of them has failed to make predictions in more than one instance and in sóme cases has missed by a wide margin. In selecting hens for layers I always select those with bright eyes, stout, thick beaks and, in cases of Barred Rocks, those with rather wide heads, with overhanging eyebrows. The health of a hen is shown by a bright red comb during the laying season. These are the head points to be observed. The color of a hen's shanks indicates how good a layer she has been. The hen that has short toe nails is likely to be a heavy layer. Once Prof. James E. Rice of Cornell had his students kill several nests that had trap nest records, and dress them. Then he undertook to select the bodies of those which had made the best records. He succeeded. He then told his students that he had made his selections by examining the toe nails and selecting those which had worn their nails shortest by scratching. These were the hens with hearty appetites and the vigor that caused them to keep busy. I once heard Prof. Rice tell his students that the hen that was out the earliest in the morning and latest in the evening was the best layer. As a rule, the hen that digs up the most flowers and garden truck pays the largest profit. Plymouth Rock of all varieties, if not carefully fed, will drop behind—"bagging dow" we call it. This is caused by an accumulation of fat, and after a hen has bagged down she is more profitable to sell than to keep for eggs. The man who makes a specialty of breeding fowls can after a while make a fairly accurate guess as to the laying ability of any of his hens. He will not be able to explain just how he arrives at his conclusions. He decides from what may be called a personal acquaintance with each individual in his flock. The hen that follows him and sings for him, is always ready to run for feed, and likes to be picked up and petted, is the one that is most profitable. Laying ability is transmitted in a zigzag way. The hen that makes a heavy record does not always transmit her laying ability to her daughters. That is, one can not count with certainty on getting his heaviest layers from his heaviest-laying hens. Laying ability is transmitted from a hen to her sons mor ethan to her daughters, and the daughters the able to transmit laying ability to their sons. For instance, a laying-bred hen that has made a record of 150 to 160 eggs in a year is more likely to produce heavy-laying daughters than one that has made a record of 200 or more eggs in a year. The son of a heavy-laying hen is nearly always the sire of heavy-laying daughters. It follows that to get heavy-laying pullets one should use the son of a heavy-laying hen, and to get the right kind of a male bird one should use the daughter of a heavy-laying hen.

FEEDING THE CHICKS

Several weeks ago, in order to test the fertility of the eggs which our hens were laying, we set a hen on an asortment of eggs. In due time the chicks hatched and as we had not secured our supply of prepared chick feed for the season we gave them wheat and sour milk. The wheat consisted of small grains screened out in recleaning wheat for seed. In this country there are no weed seeds in wheat as it comes from the machine but there are broken and shrivelled grains, so the feed the chicks got was just wheat and sour milk. The hen was put in a coop near a stack of alfalfa and as soon as the chicks were a few days old they begin to work on the broken leaves and blossoms scattered about. When the chicks were a week old the hen was turned out after the sun got up to warm the air. These chicks are now five weeks old and as hear ya lot as we ever had. They run in and out of the poultry houses at will and probably get some of the meat scrap which the laying hens have before them. They also get new grass if they want it, but I have never seen them picking at it.

This shows that chicks from the eggs of vigorous hens are hardy and get along on a very simple diet. This morning there was a light snow on the ground but the chicks did not mind it. They wer out and about as soon as the sun was up, digging away as if they liked it.

We have never paid much attention to complicated formulas in feeding our chicks. If they are all right when they come out of the shell they get along very well on the kinds of feed which the average farm suplie. If they can have sour milk from the beginning they grow on almost any kind of grain, if it is small enough so that they can swallow it. If I could get sound cracked corn I would feed it without any fear, as long as I had sour milk to feed with it. Cottage cheese made exactly as it would be for the table is most excellent feed to use two or three times a week in connection with the plain sour milk. It is very rich in protein and builds up the muscles and bones while the corn supplies the energy and fat. In these high-priced days, when it is so neoessary to keep up and even increase the poultry stock of the country, we must get along without any frills on our feeding operations, and when we can save money in feeding it is our duty to do so. Elaborate rations are all right in normal times but now we must use the cheaper substitutes that are available on every farm.—Miller Purvis.

THE POULTRY CALENDAR

For Feeding and Watering

In poultry raising there is, as ordinarily practiced, a great waste of water and feed. Wasted water fouls the litter and the floor and makes insanitary quarters; wasted feed cuts deep into any possible profits that might accrue. Careful estimates and experiments tend to prove that perhaps twenty-five per cent of mashes, wet and dry, fail of their purpose when fed in open troughs or pans. Not only is costly feed scattered by the hens among the dust and litter that cover the floor, but greedy birds get into the vessels with unclean feet and the resulaing mess is not eaten. I have seen wet mashes packed by repeated tramplings so that half was lost; and water becomes sewage.

To avoid such conditions and at the same time to conserve as much floor space for the use of the birds as possible, we place our water pans and wet mash containers on stands. We settled upon a water pan of galvanized iron four feet long, four inches deep and eight inches wide as most convenient for our purpose, and the stand to support it is made in this way:

We take two one-and-one-half-by-two-inch pieces twenty-six inches long, two one-by-two-inch pieces twelve inches long and one piece twenty-two inches long, and two one-by-one-inch pieces ten inches long. These are nailed together to make a standard, and two standards are used for each stand. Two twenty-six-inch pieces, for legs, are laid down, spaced twelve inches over all, and the twelve-inch pieces are nailed on, one across the top and the other eight inches from the ttop. The open space between the cleats is thus six inches. The twenty-two-inch piece is next nailed on eleven inches from the lower end of the legs, but on the opposite side from the cleats already nailed, and projecting five inches over each side, thus forming a ledge on which the platform is laid. The two pieces one inch square by ten inches are nailed vertically on the upper cross pieces, spaced one inch from a slot to receive the end of the parting board.

Birds Stand on Platform

For the platform, a board one by eight by farty-nine inches is nailed on the ledge of each of two standards, fitting between the legs and separating the standards a little more than forty-eight inches to make it easy to remove the four-foot pans; a board one by six by fifty-four inches to make it easy to remove the four-foot pans; a board one by six fifty-four inches is nailed on each pair of projecting arms. On this the birds stand while eating or drinking.

In the slots formed by the vertical pieces a board one by six by fifty inches is fitted. This board may be nailed or not, as preferred. A shoulder is sawed out at each end of the board so it may drop within an inch or two of the top of the pan; then by nailing against the strips the stand becomes very firm. This board is a very importan feature of the device, as without it the birds persist in getting into the feed or water, creeping too and fro constantly.

A cover one foot wide by fifty-four inches long, cleated at the ends to keep it in place and to serve as an additional steadying help, is laid over the top of the standards and the thing is complete. The cover prevents fouling from above; the parting board keeps unwary feet from straying into the pans; the height from the floor keeps all litter from feed or water, and leaves the floor unobstructed.

The galvanized pans, while intended primarily for water, are equally good for feeding mash, especially wet mash. For feeding purposes, however, it is well to board the platform over tightly so that whatever is thrown out need not be wasted.

Though the metal pans are in every way best for water, they are somewhat expensive; therefore for feed alone we substitute V troughs of the same length. For cramped quarters we find a modification of these stands useful. It is a double deck affair. The standards are made higher, with two platforms—one below to receive a water pan and the other to receive a V trough for feed. It works to perfection.

These stands are a part of the outcome of our campaign to free the floors of our poultry houses of everything, that heretofore cluttered them. The birds need all the room, and cleanliness demands that there shall be no inaccessible places anywhere.

For feeding purposes alone we use these stands up to sixteen feet long. Long stands, however, have a third standard in the middle to support the trough and cover.

HOWARD MITMAN.

PEDLAR'S GEORGE SHINGLES

Lightning-Proof

THESE shingles lock on all four sides, forming practically a one-piece roof of heavily galvanized steel, which, when properly grounded, causes lightning strokes to be evenly and harmlessly distributed. Proof also against fire, wind, rain or snow, and will not rust or decay, but will last a lifetime without need of repair. See your dealer or

THE BRAVEST BATTLE

The bravest battle that was ever fought.
Shall I tell you where and when?
On the maps of the world you will find it not;
'Twas fought by the mothers of men.

Nay not with cannon or battel-shot,
With sword, or nobler pen;
Nay, not with eloquent word or thought,
From mouths of wonderful men.

But deep in a walled-up woman's heart.
Of woman that would not yield,
But bravely. silently bore her part—
Lo—there is that battlefield.

No marshaling troops, no bivouac song;
No banners to gleam and wave!
But oh. these battles they last so long—
From boyhood to the grave!

Oh! ye with banners and battle-shot.
And soldier to shout and praise,
I tell you the kingliest victories fought,
Are fought in the silent ways.

THE LIGHT-FOOTED MOTHER

(By Stella Burke May)

Ellen Malone rubbed her wrinkled eyelids with one work-broadened hand as she pushed back a wisp of hair with the other, and, opening her eyes, blinked as the sun shone upon her from the half-opened window and from cracks in the limp green shade.

"Seven o'clock!" she exclaimed, the accusing hands of the cheap clock on the bureau pointing shamelessly to this unwonted hour of rising. "Seven o'clock! An the sun an hour high. Whatever's come over me, and it Tuesday and the Finlaysons' ironin' all folded down. and Annie's confirmation dress to be finished, and Johnnie out of shirts entirely, and school openin'!"

"Annie! Johnnie" she called, but received no response from the younger Malones sleeping across the hall—Annie in the one other bedroom the tiny house afforded; Johnnie in his curtained corner of the hallway—so she wriggled out of bed and started to dress.

"Mrs. O'Hara was right," she remarked to the tired face in the mottled wall mirror;—" 'A light-footed mother makes a heavy-footed daughter'— and son ,too." she added to Mrs. O'Hara's maxim. " 'Twas not so heavy-footed they were a-dancin' off to the Labor Day Picnic yesterday—Labor Day—h'mmm—for me—a picnic for them. Mrs. O'Hara is right, it's spoilin' them children I am, slavin' away for them at the washtub. An' them all tired out this mornin' from havin' a good time; sleepin' till I call them to breakfast. O, ho," and she sighed; "if himself had lived it's a different life I'd be havin'. I'd like to see how a holdiay'd feel." glancing longingly at the bed.

Ellen Malone walked to the door of her room and listened cautiosly. The steady, even breathing of peaceful slumber came to her from Annie's room while Johnnie snored blissfully. A cool. September breeze fluttered the curtain, as though saying, "Come on, Mrs. Malone, I'll making ironing day easy fo ryou, for I'll blow between you and the stove so you'll hardly mind it at all." The sunlight trickled in a wiggly path across the bare floor, giving promise of its aid in the process of bleaching. But the few seeds dropped yesterady by neighbor O'Hara out of her sack of experience, as the two women compared the fruits of their labor, had taken root and were beginning to sprout.

"Shure, as long as you carry thim children on your back, they'll niver learn to walk," was Mrs. O'Hara's remark. "Children are all alike," she had added; "if you do their work for them, they'll leave you do it. 'Tis a light-footed mother that makes heavy-footed children. Taach thim to walk alone!"

Mrs. O'Hara knew. Ellen Malone, that was born Ellen Conley, was always light of foot. Lightly she had tripped over the peat bogs of her natlve village in Ireland. Lightly she had picked her steps down the gangway to Castle Garden; llghtly she had danced in to the heart of Daniel Malone. And with nimble foot, though her heart was heavy within her, she had assumed life's responsiblities and the care of her little family when "himself" was laid to rest. This panorama flitted across her mind and reflected itself in her miror as she turned again to look at the face that had once been the rosy-cheeked Ellen Conley. Suddenly she grew very, very tired, and the tumbled bed with its faded blue quilt looked very, very comforting and welcoming. Once more she listened for some sound of awakening from the young people, but none came, and without daring to argue with Conscience, and before she fully realized what she was doing, she had slipped off first one run-down slipper, then its mate, and ere the still, small voice had caught its second wind, she was back in bed with the covers pulled up close around her neck and her face turned to the wall. Morpheus, put to rout at seven o'clock by the September sunshine, beheld from afar the droopy eyelids. He returned, sat upon her bedpost, found himself endured. then pitied, then embraced.

At eight-thirty Annie Malone awoke and listened. They say that people who live near the sea find sleep impossible when they spend a night away from the lulling sound of the waves on the shore. It must have been the missing of the splash of water in the Malone kitchen that awakened Annie. There was no swish of clothes as they flopped from the suds to rinse water; no rattle of pans that accompanied the starch-making process. There was not even the odor of coffee boiling nor the sizzling of potatoes frylng.

Annie crawled from bed and looked across the hall to her mother's room. A slender form on the bed, swathed in a tightly drawn quilt, startled her.

"Ma. are you sick?" Annie called. But no reply came from the slumbering woman. "Johnnie, Ma ain't up!" she called to her brother. "She must be sick or something."

By degrees the full import of this announcement struck in upon the waking youth, and the first thought that came to him found utterance:

"Gosh! and who'll get breakfast!" It was the first time ln Johnnie's fifteeen years of eyperience that Ma had afiled to have his breakfast on the table when he clattered down stairs.

Johnnie stretched and yawned and pulled himself out of bed and together they went to their mother's room. Ellen Malone dreaming of care-free days of youth opened her eyes and regarded her two young hopefuls.

"Ma you ain't sick!" came in one breath from both but Mrs. Malone only raised her hands to her temples as though unable to bear any sound and said: "Sh-sh-sh. G o'way go 'way" and once more truned her face to the wall.

Puzzled the children went back to their romms — if Johnnie's corner might be called a room, and dressed.

Annie was almost seventeen, but she had never prepared a breakfast unaided in her life. Annie was fitting herself to be a school teacher, and embryo school teachers had no time for household tasks. Annie was very fond of her mother; so was Johnnie; but Mrs. Maione always had prepared breakfast so how could they learn! Annie sometimes washed the dishes, under protest, of course, but still sometimes she did wash them, always arguing that "Johnnie ought to be made to wipe, like Jimmy O'Hara did"; but Johnnie was an elusive chap after meals, and Mrs. Malone was too busy or too tired to call him; besides, Johnnie always carried home the clothes after his mother had piled them neatly in the basket and "Gee, whiz it's a long way to Finlayson's and a felow has to have some time to play with the boys!"

Annie had never dressed hurriedly nor did she now, but in justice to Annie let it be said that she dressed less deliberately than usual. Then she went down stairs, and, passing through the kitchen—how cheerless a kitchen is without a mother and a fire—went over next door and told Mrs. O'Hara that she guessed Ma must be sick, "'cause she isn't up, and its after eight o'clock." Mrs. O'Hara was surprised, honestly surprised, and came right over and went to Mrs. Malone's room. Ellen Malone turned over, saw Mrs. O'Hara, and the effort of turning must have distressed her greatly for her mouth dropped at the corners, her eyes rolled ln evident anguish, and again she lifted her hands and pressed them to her temples; but Mrs. O'Hara who had raised eight children and three husbands, and knew a great deal about human ills and human nature, discerend at once the seriousness of the ailment; in fact, there was not a doubt left in Mrs. O'Hara's mind when she saw, just as Mrs. Malone's fingers closed over her right temple, that she winked her eye.

"Rest and quiet!" she prescribed for the patient to Annie, who stood gloomily just inside the door, and to Johnnie who stood just outside.

"Oh, dear," said Annie, "I've a headache myself this morning."

"You'll feel better after breakfast," her neighbor assured her; better make some coffee for your ma; it'll be good for her."

Behind the kitchen door Annie found her mother's apron, and started to make a fire ,but the wood-box was empty.

"Go spilt some wood," she stamped impatiently at Johnnie.

"Jimminy crickets, ain't there no wood? I split some Sunday."

Ma Malone had always chopped the wood the first thing each morning after she fed the chickens, but Johnnie didn't know that, of course, becauase Johnnie wa snever awake then. Occasionally Johnnie chopped some before supper, if he was within hearing distance of his mother's call; but yesterday was Labor Day and no one worked that day; no one but Ma Malone. He couldn't find the axe, and had to go upstairs to ask his mother, who told him, in a pained voice, just where it was in the shed kitchen.

It was not as restful a morning as it might have been for the tired litttle woman up stairs, because there were necessary questions from below; how much coffee to put in the pot; were there any cold potatoes to fry; did she know the bread was out; where was any money for Johnnie to go to the store; Mrs. O'Hara says the Finlayson's clothes will mildew if left in the basket this warm day, and what's to be done about it?

The school-bell rang just as Mrs. O'Hara—who kept popping in at ten-minute intervals—was about to impress Johnnie into the washing of the dishes, and never did Johnnnie start for school with such willing feet.

Annie was very sad at the enforced absence on the first day of the school year, but at Mrs. .O'Hara's "Tut! Tut! An' your poor Ma sick in bed," resigned herself to the inevitable.

It was a weak, flat cup of coffee, and sad, flabby potatoes and an ebony-hued piece of toast that found their way to the mother's room for breakfast, but she ate them so greedily that Annie who never could eat when she had a headache, feared a relapse and so told Mrs. O'Hara; but the kind-hearted neighbora reassured her, saying: "The trouble ain't so mcuh in her head as her feet." This was a surprise to Annie, who had understood that her mother's trouble was entirely in her head; bu tMrs. O'Hara said: "It's a

ACADIA UNIVERSITY
WOLFVILLE - - Nova Scotia.
Departments
Arts and Sciences. Applied Science. Theology.
Degrees
B.A., B.Sc., B.Th., M.A., and certificates admitting to the best technical schools. First two years in Agriculture given as electives in B.Sc. course. First year in Medicine, Law, and Theology given as electives in B.A. course.
Special Courses
Courses in Surveying, Draughting, Shopwork, Chemistry, Electricity, and Bacteriology, for returned soldiers and men anticipating military service.
Equipment
Largest undergraduate faculty in the Maritime Provinces. Three new and splendidly equipped Science Buildings.
Expenses
Expenses light, and over $1,000.00 given in prizes and scholarships yearly. Send for calendar to
Rev. GEORGE B. CUTTEN, Ph.D., D.D., LL.D., President.
Next term begins Oct. 2nd, 1918.

ACADIA LADIES' SEMINARY
WOLFVILLE - - Nova Scotia.
The Aim.—To prepare Girls and Young Women for Complete Living.
The Courses.—Twelve; including College Matriculation, General, Music, Art, Expression, Household Science, Business.
The Faculty.—Twenty-four Teachers of fine personality and Special Training.
The Equipment.—Modern and First Class in every respect.
A Junior School.—For Younger Pupils.
Information.—Write for illustrated book to
Rev. H. T. DeWOLFE, D.D., Principal.
Next term begins Sept. 4th, 1918

Butter Parchment at Farmer Office

little of both, but it's mostly in the feet—they've been movin' too fast."

Upstairs Ellen Malone was struggling with her mother heart, which was uttering a protest against Annie's missing a day of school; aand she might have yielded but for the timely arrival of Mrs. O'Hara.

"They'll never walk if you carry thim," she whispered. "Take it easy; it may be your last chance."

By noontime all Crowley's lane was aroused to th efact that Ellen Malone was sick and the childrei had been doing her work—or their own.

"Ellen Malone's a-dyin'! Ellen Malone's a-dyin'! She'd never stay in bed if she wasn't near to death's door," spread from house tot house, and excited mothers and sympathetic wives filled the kitchen.

Annie surprised everyone, but herself most of all, by the array of stiff, smooth garments that stood out from the greedy clothes-horse. True, she had a good teacher in the person of her alert neighbor, who was never too far away from the opposite window to answer the many questions shot from the Malone kitchen, such as how to make cold starch ,did she iron sleeves on the right or wrong side, and numerous others.

The stove called constantly for more fuel and by the time Johnnie came home to dinner, his morning's stack looked like Mother Hubbard's larder, but Annie refused to give him any dinner until he split more wood. His back ached and he was hungry, and the meal of watery cabbage and underdone beef was not just what Mother used tomake. Moreover, the baked custard that Mrs. Murphy's little Jennie brought over for the invalid spoiled his appetite for substantial foods, and caused him to remark to his sister after seeing the dainty dessert disappear spoonful by spoonful at the hands of the sick mother: "Seems to me like Ma has a pretty good appetite, if she is sick. She ate that custard like the O'Hara kids at the picnic."

But when Father Donahue came in the afternoon, he shoook his head gravely and, after a whispered conversation with the next-door neighbor, announced to the children: "Your mother needs rest; she's been working too hard."

By four o'clock Annie was hot and tired and Mrs. O'Hara offered to "spell" her awhile at the board while she mended Johnnie's Sunday pants, saying:

"That's the way your Ma rests herself, mendin' and sewin', when she's tired wid ironin' and scrubbin' and bakin'. Go up and sit beside her wid your mindin'; it'll do her a dale o' good." And indeed it must have done good, for after one glance at Annie with hte mending basket, Mrs. Malone smiled and turned her face away and slept.

Johnnie did not return until supper time. He was accompanying Torchy Halligan on his paper route. It was a long route and took the boys to the outskirts of the town, and dusk began to fall before all the papers were "chucked" down a convenient sewerhole and husbands and fathers, returning home that night and finding no evening paper to peruse, broke the second commandment. But Trochy and Johnnie trudged on unsmitten by conscience.

After Johnnie had eaten his bread and milk, and carried tea and toast to his mother's room. Annie insisted on his taking home the Finlayson's clothes.

"I won't go a step; I'm tired." Johnnie announced.

"You will go; I've worked harder'n you all day," the elder sister replied.

"Well, it' sthe first time you ever worked, that I can remember." Johnnie retorted, adding, "No wonder Ma's sick, the way she works for you."

"Cry shame to yourself," interposed a voice, entering by the rear door, and bringing with it the ample form of Mrs. O'Hara. "Sure, Johnnie boy, if you didn't leave your Ma to split the wood and carry the water and coal, it'd help a little, too."

So Johnnie carried the clothes to Finlaysons', and returning, spiritually uplifted by a chance meeting of Father Donahue, chopped wood and filled the water paial and brought in a hod of coal. And Mrs. O'Hara, saying her beads that night, named one for Johnnie as well as for his mother and sister.

Two very weary young people bade their mother good night at the close of that workaday Tuesday.

"Good night, ma; hope you'll be well in the morning," and they meant it, too.

Johnnie's back ached from the unwonted labor, and he passed a restless night. Some time before midnight he arose to see if he could find some sort of liniment to take the twinge from the right shoulder, where the unused muscles were protesting, but, hearing a creaking on the stairs, he listened breathelessly for a few minutes.

"Burgulars!" he told himself, and remembered that he had left the two dollar bill Mrs. Finlayson had given him for the washing, on the shelf in kitchen cupboard. His heart thumped ae he waited, and then he heard the creak of the cupboard door, opened by stealthy fingers. It was some time before he could summon enough courage to approach the stair railing that commanded a view of the kitchen. But at last he gathered himself together for the supreme effort, and took three cautious steps, which brought him to the railing. For several minutes he watched. What he saw was not a burgular in the act of appropriating the two dollar bill. But it was something much more disquieting; so disquieting that, though he felt his way cautiously back into bed, making no sound, he lay awake for a long time, thinking, studying.

In the morning Johnnie arose at six o'clock and tip-toed to his mother's door. She appeared to be sleeping. He cautiously approached his sister's bed:

"Sis," he whispered, shaking her shoulder, "Sis, you'd better get up," and as her eyes opened he put his fingers to her lips and cautioned silence. "Sh-sh-sh!" he whispered, "ma's puttin' somethin' over on us. She wasn't sick at all yesterday. I saw her down stairs last night, well as could be, eatin' a sandwich as big as your head."

Then he went back to his room and dressed. Annie dressed too, dressed very quickly, and as she dressed yesterday's suspicion straightened itself out into a reality.

"Ma, are you going to be able to get up today?" queried Annie, impatient with fear of the reply.

"What! You up?"

"Yes, and Johnnie's down stairs already. I think he's emptying the ashes."

"Indeed? Why, yes. I think I feel better this morning; I believe I can get up," and a deep, relieved sigh escaped from each.

Mrs. O'Hara came over while the

YOUR CUP OF TEA

Your cup of Tea means much to you. It is more than an item in the daily fare. It is the one thing that "rounds off"—or spoils—an enjoyable repast.
Tea is fortunately so cheap in this country that there are few who cannot afford *Choice Tea*. The cost per pound is only slightly higher than ordinary Tea, while the increased pleasure you get from every cup you make is worth many times the difference. It is true also, that a FLAVOR-FULL Tea like KING COLE Orange Pekoe will actually spend further—that is, make more cups to the pound. KING COLE Orange Pekoe is prepared particularly for lovers of Choice Tea.
UNUSUAL QUALITY - EXCLUSIVE FLAVOR

family were eating the breakfast that Annie had helped prepare, while Johnnie fed the chickens and raked the patch of green they called a lawn.

"The saints be praised, you're better Ellen Malone!" the neighbor exclaimed, rejoicing, indeed.

"Yes," came the rejoinder, "but my feet still feel a bit heavy this morning."

"Well, niver worry," Mrs. O'Hara replied. "Annie's are gettin' much lighter. And as for Johnnie; sure, it's the regular fawn he's becomin'!"

THE NEW DOUBLE KNITTING

Two Socks at Once on Four Needles

Materials required: Two 2-ounce balls of knitting worsted and four steel needles, No. 12. Size 11—Cast on 60 stitches, 20 on each of three needles, and knit 2 purl 2 for 35 rounds. Then make the top for the other sock just as directed for the first one. Put one sock inside the other. On the outside of the sock purl all work; for the inside of the sock knit plain.

First row—Silp one stitch alternately from each sock. Now you have 40 stitches on each of the three needes. Make the twentieth stitch on tho first needle the seam stitch. Now work 30 rounds, knitting plain on the inside of sock and purling on the outside of the sock, having two separate balls of yarn and knitting from one for the outside.

Knit 1 stitch with a thread from one ball and purl the next stitch with a thread from the other ball and continue in this way all through the sock. When you reach the seam stitch knit instead of purling on the outside, purl on the inside instead of knitting, and then continue the rest of the row as directed. Work for 30 rows. Then decrease on each side of the seam stitch on the inside sock and on the outside sock, taking 2 purl stitches together on the outside sock and knitting 2 stitches together on the inside sock on each side of the seam stitch. Repeat the decrease every tenth row and make three sets of decreasings, making 28 stitches on the needle on which you have been decerasing, instead of 40 stitches as the other two needles hold.

When the work measures ten inches from starting point start the heel on the needle on which you have been decreasing and add 10 stitches from each front needle, which makes 48 stitches for the heel and 30 stitches on each front needle. Heel—Continue to work as you did for the leg of the sock, purling on the outside and knitting on the inside with the two balls of yarn. Work the 48 stitches for 20 rows. Then work 36 stitches and decrease, knitting 2 together and purling together. You will have to change the stitches a little in order to do this, as the socks must be kept separate. Turn the work and work back until you have 12 stitches unworked on the needles. Then work 2 together as you did on the row before, and repeat this at the same place until the heel is all worked. Pick up 20 stitches on the inside and the outside of each side of the heel. Now arrange them on one needle as you slipped them on when you started the double sock. Hold threads tight at the corners where the gores begin o rsmall hole may result. Darn if necessary. Decrease each side every third row until there are 120 stitches on the feet, 30 on each side needle and 60 on the front needle. Work 55 rows as you did for the leg.

Now take the socks separately and finish as you did for the single sock. The feet should measure nine inches from the back of the heel.

First row for the toe narrowing—Knit 6, knit 2 together, knit 6. Repeat for one round. Knit six rounds without narrowing. Knit 5 stitches, knit 2 together, knit 5 and continue for one round. Knit 5 rounds without any narrowing. Knit 4 stitches, knit 2 together, knit 4 and repeat for one round. Knit 4 rounds without narrowing. Continue in this way until there are 24 stitches left. Divide on 2 needles, 12 on the front needle and 12 on the back needle. Finish with a Kitchener toe.

THE CHILD'S EYES

There is a picture by Watts representing an old man sitting in a chair asleep, with all the implements of his work before him. Death near him touches him on the shoulder, and in his hand Death has a child, ready to take on the od man's work.

It is the children of to-day who will make the community of to-morrow. Thus can be seen the great importance of looking carefully after the children in order that they may grow up strong men and women without handicaps, prepared to take our places as soon as they must in the various walks of life.

Success and safety in life depend to a great extent upon the care of a child's eyes.

The increase in the number of young people suffering from eye-strain shows that much popular education is needed concerning the care of children's eyes.

New-born infants are very sensitive to bright lights either natural or artificial. They should not be subjected to a strong light for two or three weeks. A young child should never be allowed to face the sun, as this will cause the habit of squinting and may be productive of serious defects of vision. Nurse-maids who take young children out into the open should be thoroughly instructed on this subject.

In the bedroom and nursery neutral and dark tints should be used, but never white. If a white parasol is used over a carriage, it should be lined with a color, preferably green.

During such infectious diseases as scarlet fever, whooping-cough, and particularly measles, the eyes should be carefully protected. For the first few days have the room moderately dark, as at this time the eyes are abnormally sensitive to light. Hot compresses of boric-acid solution will relieve pain. During the convalescent period, avoid strain by use and keep the child on a low diet.

A young child should not be allowed to look at anything requiring close vision for a long time, as the so-called fusion of the vision develops very slowly in young children. It is not fully acquired until the age of seven to ten. If the eyes are used for close application before this time, it is apt to cause near-sightedness.

When school age is reached and studies are begun, the letters should be large and the lines short, with considerable distance between the lines. The periods for using the eyes should be short.

The child should be taught to hold his head up when reading and to hold the book from twelve to fourteen inches from the face. The habit of holding the book too close to the eyes is easily formed. This will cause a strain of the muscles both within and on the out side of the eyeball and is a cause of near-sightedness.

The mother should be careful to see that a child just beginning to study does not abuse his eyes by too long-continued use or by improper light.

Some of the earliest principles to teach a child just beginning to use books are: Never to sit facing the light but to let the light come from behind or over the left shoulder; to avoid books or papers printed indistinctly or in small type; never to read in the tiwlight or in a reclining position or with the sun shining directly on the book. In any close application of the eyes, teach the child the necessity for frequently resting them by looking away from the material or book and letting the eyes rest on distant objects.

There is nothing so restful to the eye as the foreground of Nature. It is painted in colors least apt to tire the eyes, and in viewing it there is a constant unconscious relaxation of the muscles of the eyes.

For this reason alone, and there are many others, the child attending school should never be deprived of his hours of play in the open after school-hours.

There are many children who need glasses at an early age. Even normal vision does not preclude eye-strain.

A medical writer on this subject has said: "Eye-strain is the more easily overlooked because it often accompanies perfect vision, and, paradoxical as it may seem, is much more likely to follow small errors than large ones. The one who has a very large error strains for clear vision, but after a time ceases because it is of no avail and is contented with limited vision, while the one with small error often continues straining because it enables him to see distinctly."

It is not unusual for eye-strain to cause reflex disturbances in distant parts of the body. During the early school age, should there be unusual restlessness, headache, irritability or gastro-intestinal disturbances the mother should think of the eyes as a possible cause.

The child who is near-sighted will be unable to see blackboards or other distant objects used in teaching. As near-sighted eyes tend to become worse if nothing is done to protect them, seriously impaired vision may be the result.

The far-sighted child suffers from headache in his efforts to see near objects and, unless relieved by glasses, not only will his health become impaired, but he is very apt to become careless and shiftless in his school work.

If a cross-eye should appear in a young child, he should be put into the hands of a competent physician at once, who will at once retract it. This should not be neglected as it is a question of preserving the sight in an eye that may otherwise become practically useless.

Pinkeye is a common infection among school-children. It is marked by redness of the eyes; a muco-purulent discharge and a feeling as if

PALMER'S Summer Packs for the S.O.S.

The "Soldiers of the Soil" recruits need Palmer's Summer Packs, or plough Shoes as they are often called, to keep their feet in good condition while doing hard farm work which their feet are not accustomed to.

Even farmers whose feet are hardened to farm labor find Palmer's Summer Packs very restful to tired, aching, burning feet. They are light in weight, roomy, pliable, comfortable, durable and waterproof.

Get a pair from your dealer. Look for the "Moose Head Brand"—stamped on every pair—a warranty of satisfaction.

JOHN PALMER COMPANY, LIMITED
Fredericton, N.B., Canada 86

Honorably Discharged

From Canadian Army and R.N.W.M. Police on Account of Weak Heart.

Mr. Victor A. Tatton, Indian Head, Sask., writes: "It is with pleasure I am writing to let you know that I have been cured of weak heart by using Milburn's Heart and Nerve Pills.

I had been a sufferer for nearly two years with heart trouble and could get no relief by using other kinds of medicine.

I had been in the Canadian Army for nearly ten months and was honorably discharged on account of my heart.

I served in the Royal North-West Mounted Police, in 1917, and was also honorably discharged on the same account.

A friend of mine advised me to try your pills. After taking three boxes I was completely cured. You can please use this as you see fit."

Wherever there are people suffering with weak hearts, they can find no remedy that will do so much to make the heart regain strength and restore it to a normal and healthy condition as Milburn's Heart and Nerve Pills.

Price 50c. a box at all dealers, or mailed direct on receipt of price by The T. Milburn Co., Limited, Toronto, Ont.

grains of sand were sticking under the lid.

This is highly contagious. The child should be kept from school and should not use the eyes as long as there is any inflammation present. Any article that may come in contact with the child's eyes should be strictly isolated to prevent its spreading to other members of the family.

This usually lasts from ten days to two weeks and terminates favorably. Apply cold compresses to the eyes in the initial stage and call in a physician.

When it is suspected that a child has imperfect vision consult a competent oculist.

This needs special emphasis, as there are many opticians and would-be oculists whose chief concern seems to be to sell glasses. Do not practise economy on the eyes by trusting them in the hands of an incompetent man.

HAVING REGARD FOR ANOTHER'S REPUTATION

Kindness brings peace and joy and if every person always tried to be kind the world would be truly improved. But we find many who do unkind things purposely, yet many times unthoughtedly.

It's unkind to criticise our neighbors for what they do. If we were in their places we would likely do just as they do. We would be doing them a kindness if we minded our own affairs for they can attend to theirs much better than we can. We can cheer our friends along life's way by a friendly deed, an encouraging word, and a smile. As we journey through life we find many obstacles which hinder our progress. Our friends find the same. Thus their lives are just as full of storm with occasional gleams of sunlight as ours are. We know by sad experience how trying some moemnts are, and how hard to bear are the cares these moments bring. Knowing this, we should pity, instead of finding fault with those who, we imagine, are making little effort to do what is right and just. Perhaps they think the same of us, and if we could see ourselves through the eyes of others, we would be sorry we did not try to correct our own faults before we thought of correcting those of others.

It is very unkind to speak untruthfully of another. A person who speaks untruths is much more to be feared, than one who covets our worldly possessions. Our good reputation is often ruthlessly torn from us by the person who cannot or will not tell the truth. Untruths spoken of innocent people have caused much trouble and brought so much unhappiness. Joy has been crushed out of many a singing heart because of careless conversation. And then comes the repeating, and each word is sometimes multiplied several times, until at last a mountain has grown from nothing. Christianity means much more than simply being a church member. To be true Christians we must follow in Christ's footsteps, which means that we must not gossip or tell untruths, nor stir up strife in the neighborhood.

It's so much kinder when entertaining or visiting a friend to discuss some interesting topic of the day, rather than spend the valuable time in enumerating some person's short-comings. Nothing is gained by evil conversation and time spent in fault-finding is lost. The priceless moments in which we might have accomplished something good have flown forever beyond recall. Many opportunities, golden opportunities, for doing kindness have drifted far into the unreturnable past.

Let us try to be kind to all. In so doing we will surely learn the true value of kindness.

A WHITE THROAT

So many girls complain that their necks are discolored! And men too—oh, in long letters, apparently quite surprised that they can keep a nice complexion so far as the face is concerned, but can do nothing for the neck.

And wouldn't they be surprised if I told them that the main trouble was just—dirt. And offended, too—I'm afraid they would never write to me again. Yet plain everyday dirt is the cause of most discolored necks.

Consider—the neck is almost as exposed to dirt as the face, yet is never washed as often nor as thoroughly. Besides, the collor rubs loosely against the skin and grinds in the dirt particles deep into the pores. Or colored material comes against the neck of necklaces, which collect and rub in a surprising amount of dirt—or fur, which is another dust collector and frequently full of dye.

Do you wonder, then, that the neck gets brown and homely? And all it needs is a little extra care and protection.

First of all, give it a washing with soap and hot water, and hold a hot, wet towel around it a moment, to open the pores. Then rub in a cleansing cream—this advice is for men as well as women—and rub the cream round and round till you have worked it well into the pores. And then wipe off on a soft clean cloth—and you'll be shocked at the amount of dirt that comes out. Also, you'll be pleased at the whiteness of your neck.

So much for care—this treatment should be given about twice a week, with a cold rinse or an ice rub to end with, so as not to catch cold. Using cucumber milk or lemon juice on the neck now and then will keep the skin creamy white, provided it is quite clean.

For protection—never let colored goods come against the neck. If you wear furs, wear a white collar over your suit or gown or even a chiffon scarf, to keep the dark fur away from direct contact with the skin. Wear a white or very light collar over your coat, so it won't rub or pull the collar of the waist out over it to protect the skin. If you're a man, well-fitting soft collars for general wear will be easier on the neck than stiff starched ones, and will keep the young lines of the neck for you.

If you're either man or woman don't wear high choking collars or collars that bind or restrict the neck in any way. These make the muscles flabby, and the neck wrinkled, and often hamper the circulation to such an extent that red nose results.

AFTER-DINNER MINTS

Two cupfuls of granulated sugar, two-thirds of a cupful of boiling water, one-third of a teaspoonful of essence of peppermint. Roll and sift sugar until very fine. Boil sugar and water till it makes a soft ball. Remove to pan of hot water. Add flavoring.

Take out a scant half teaspoonful at a time. Stir until it begins to look white. Drop quickly on oiled paper with a teaspoon, enough to make a patty about the size of a quarter, or pour into small patty-pans.

Have ready salted almonds cut squarely in half. Press into the center of the patties in upright position. The mint and almond made a delicious combination for after dinner.

WORTH KNOWING

When Corn Won't Pop

Pop-corn that will not pop is often too dry. If it is sprinkled with water it will pop quickly.

Opening Fruit Jars

To open fruit-jars without injury to the lid or rubber, place cans top down in tea-kettle of hot water for a moment.

Tar Stains Removed

To remove tar from linen or cotton, rub lard on spots, and a couple of hours later wash with naphtha soap.

Twice as Much Lemon-Juice

Place lemons in bowl and cover with boiling water. Let stand fifteen minutes. You will get double quantity.

Ashes for Scouring Pans

Fine ashes are excellent for scouring pans, also glasses stained from hard water.

Preventing Mold

Cut hams may be kept from molding if the cut end is wet with vinegar each time after cutting.

Paper Patterns

When opeing up new patterns, put the number of the pattern on each piece. It will frequently save much trouble in sorting patterns.

Two Layers for Biscuit

Your baking-powder biscuit will be better if you roll the dough thinner than usual, and use two cuts for one biscuit, laying one on top of the other. They will break open more easily too.

A Burnt Saucepan

Never put soda and water into an enameled saucepan that has burned, for though this will remove the burnt portions, it will also make the saucepan likely to burn again the next time it is used. Use salt instead of soda. Fill the pan with cold salt water, leave till next day, then slowly bring to a boil. The pan will be quite clean and there will be no bad after-effects.

Soap Scraps

All the scraps of soap, when too small to be used conveniently, should be put into a can, and covered with water. If cooked for awhile on the stove, this will make soft soap, very convenient for dishwashing.

Cracks in Wooden Floor

To fill cracks in wooden floor put one-half pound newspaper in three quarts water and soak three days. Then add one tablespoonful powdered alum and one quart wheat flour. Stir and boil until like cake dough. Cool and fill crack. It will harden like cement.

The Useful Corn-Popper

A corn-popper is very useful in washing any kind of berries, as it can be locked and the whole shaken in a pan of water without bruising the fruit. It is also good for toasting bread or broiling meat, its long handle keeping the face from burning.

DR. FOWLER'S

EXTRACT OF

WILD STRAWBERRY

CURES

DIARRHŒA, DYSENTERY, COLIC, CHOLERA MORBUS, CHOLERA INFANTUM AND ALL SUMMER COMPLAINTS.

It is without a doubt the safest and most reliable remedy in existence.

It has been a household remedy for 72 years.

Its effects are instaneous and it does not leave the bowels in a constipated condition.

Make up your mind to insist on getting "Dr. Fowler's" when you ask for it. Don't experiment with some no-name, no-reputation, so-called strawberry compounds that tries to sell on the reputation built up by Dr. Fowler's.

The genuine is 35c. per bottle, and manufactured only by The T. Milburn Co., Limited, Toronto, Out.

Mrs. R. Armstrong, Nixon, Ont., writes:—"Some years ago I had diarrhœa until it became chronic. I doctored with a good doctor, but as soon as I stopped taking his medicine I was as bad as ever. I became so weak I could hardly walk across the floor alone. A friend told me of Dr. Fowler's Extract of Wild Strawberry, and less than two bottles cured me to stay cured. I think it is the best medicine for bowel trouble that can be procured."

POTATOES INSTEAD OF WHEAT

The Government has asked us to eat potatoes this Summer and less bread, because of the plentiful crop and because their starchy substance makes them a good nourishing wheat substitute. When plenty of potatoes are served at a meal. we can afford to omit wheat altogether, serving no bread at all. Here are a group of new and appetizing ways which will vary the monotony of boiled, mashed, and baked, and give a new touch to the menu.

Potato Waffles

2 cupfuls boiled riced potato, 1 cupful milk, 2 teaspoonfuls baking-powder, 1 cupful flour, 3 eggs, 1 tablespoonful melted butter substitute, 1 teaspoonful salt.

Beat eggs until light, add potatoes (which have been boiled, riced and allowed to cool), butter substitute, salt and milk, then flour sifted with baking-powder. Bake at once on a hot, well greased waffle iron. Serve with maple-sirup.

RELIEF AT LAST

I want to help you if you are suffering from bleeding, itching, blind or protruding Piles. I can tell you how, in your own home and without anyone's assistance, you can apply the best of all treatments.

PILES TREATED AT HOME

I promise to send you a FREE trial of the new absorption treatment, and references from your own locality if you will but write and ask. I assure you of immediate relief. Send no money, but tell others of this offer.
Address

MRS. M. SUMMERS, Box 309 Windsor, Ont.

Potato Soup

1 Pt. sliced raw potatoes, 1 to 4 small onions, 1 qt. water, 1 pt. whole milk, pepper, salt.

Slice the potatoes thin until you have one pint, add from one to four small onions sliced thin, to obtain less or more flavor as you prefer. Boil in water until tender, add the milk, and salt and pepper to taste. Serve hot. The potatoes and onions may be skimmed and rubbed through a colander if you like.

This makes a good soup for the children's luncheon.

Potato Pancakes

3 large potatoes grated, 1 egg, 1 teaspoonful salt, 1 small onion, grated, 3 tablespoonfuls flour.

After peeling the potatoes, grate them. Add onion, grated, salt (pepper may also be added if you like it), beaten egg, and flour. Mix well and drop by spoonfuls into good hot drippings and fry until golden brown on both sides. Serve with apple sauce. These make an excellent luncheon or supper dish for meatless day.

Cottage Potatoes

4 large potatoes, salt and pepper, drippings, 1 egg yolk, bread-crumbs.

Wash the potatoes and pare them. Put them on to boil and when half done, cut them in thin slices, dip them in the well-beaten yolk, to which has been added pepper and salt to taste, roll them in bread-crumbs and fry them a light brown in some good drippings.

Russian Potatoes

6 medium-sized potatoes, 1 small onion, water, 2 tablespoonfuls butter substitute, 2 tablespoonfuls sour cream, pepper and salt.

Wash the potatoes and pare them. Dice them and put them into stew-pan with just enough cold water to cook them slowly. They should not be covered with water. Season well with pepper and salt and add the onion chopped fine. Cover and simmer until tender but they should not become mushy. Add butter substitute and sour cream (more may be added if you like it), cover and shake the pan gently. Let stand a few minutes before serving. These are good made with old potatoes but are delicious made with the new ones.

Luncheon Potatoes

Medium-sized potatoes, butter substitute, salt and pepper, cheese.

Take a number of medium-sized potatoes, scrub them well and dry. Cut them in halves and spread each half with a little butter substitute, a sprinkle of salt and pepper and lay a thin slice of cheese and pepper aetaoilnuin slice of cheese on top. Place in a slightly greased pan and bake in a hot oven until soft and brown.

Soused Potatoes

24 small new potatoes, 1 large onion, salt and pepper, 1 lemon, 6 tablespoonfuls hot water.

Wash the potatoes well but do not pare them. Boil them until done; remove them from the fire before their skins break open. Peel and put in a large dish. Make a sauce of the onion sliced very thin, the juice of the lemon, salt and pepper to taste, and hot water. Some chopped green pepper may be added. Stir this mixture well and throw over the potatoes. Let them stand at least an hour and stir once in a while. Serve when quite cold.

Old Dutch Dish

6 potatoes, 9 apples, salt, 3 tablespoonfuls maple-sirup, ¼ lb. sliced bacon.

Pare the potatoes and quarter them, wash the apples but do not peel, core them and quarter them, and put in a stew-pan with just a sprinkling of salt, maple-sirup, and bacon. Cover with cold water and cook very slowly for three hours. The apples and potatoes should retain their shape and must not be allowed to cook to pieces. A fine dish for a camp.

Swedish Potato Balls

2 cupfuls mashed potatoes, salt and pepper, few gratings of nutmeg, potato flour, parsley, 1 teaspoonful butter substitute, 1 egg yolk, 1 tablespoonful grated cheese, white sauce.

Pare and boil the potatoes until tender, mash them and season well with salt and pepper, nutmeg and butter substitute; add beaten egg yolk and cheese and mix thoroughly. Mold into balls about the size of walnuts, roll in potato flour and drop into boiling salted water. Cook about 10 minutes, drain and put in a serving dish, pour white sauce over and top with a sprinkling of chopped parsley.

Savory Mashed Potatoes

6 medium-sized potatoes, 2 tablespoonfuls butte rsubstitute, 1 teaspoonful salt, 1 small onion, chopped, ¼ cupful cream or milk, few grains pepper.

Boil t hepotatoes, drain and mash, add butter substitute, cream or milk, salt, pepper, and last, beat in the chopped onion lightly. This will be found a great change from the ordinary mashed potatoes.

Stuffed Potatoes

6 medium-sized potatoes, 1 teaspoonful butter substitute, ½ cupful milk, 1 cupful grated cheese, salt and pepper, paprika.

Scrub potatoes and bake until soft. Cut them in halves with a sharp knife and remove cooked potatoes to a bowl. Mash and add the butter substitute, milk, ¾ cupful of grated cheese and salt and pepper to taste. Beat with a folk until light and creamy and refill potato skins. Dust the top with remainder of grated cheese and sprinkle with paprika. Return to oven until crisp and brown on the top. This makes a fine luncheon dish.

Potato Salad with Onion

4 ucpfuls sliced boiled potatoes, 1 small onion chopped, ½ cupful weak vinegar, 2½ teaspoonfuls salt, 1 hard boiled egg, pepper to taste, 4 tablespoonfuls salad oil, 4 stalks celery, 2 tablespoonfuls chopped parsley, sprinkling of paprike.

Put chopped onion in a bowl with salt and vinegar and let stand a few minutes; then slice potatoes while warm into this and mix thoroughly. Add oil, taking care not to break potatoes, celery cut fine with a sharp knife so there will be no strings to chew, pepper and 1½ tablespoonful of parsley. Mix well, cover and in a few hours mix thoroughly again. Cover and set in a cool place until ready to serve. Arrange on lettuce leaves on a platter and cover top with chopped hard boiled egg, the remaining parsley and a few dashes of paprika.

Potato Salar without Onion

1 qt. small boiled potatoes, ½ cupful vinegar, 2½ teaspoonfuls salt, 2 hard boiled egg yolks, water, 1 raw yolk, 1 tablespoonful celery seed, 3 tablespoonfuls salad oil.

Mix salt, vinegar and a little water while potatoes are still warm and slice them into this mixture. Do this right after breakfast, at noontime add the celery seed and mix gently through the potatoes, taste potatoes to see if they are salt enough, if not add salt to your taste. Cover and keep in a cool place until an hour before serving time, then prepare the following dressing. Mash the yolks of the hard boiled eggs until perfectly smooth then mix thoroughly with the raw yolk and stir until there are no lumps. Gradually add the oil and when well blended, pour over the potatoes and mix well. The recipe does not call for pepper but may be added if you like it. Serve on green lettuce leaves. This is a delicious salad and a boon to those who do not eat potato salad because they can not eat onion.

Potato Flour Sponge-cake

4 eggs, ¾ cupful sugar, 1 teaspoonful almond extract, ¾ cupful potato flour, 1 teaspoonful baking-powder, pinch of salt.

Beat the yolks until thick and lemon-colored; add a pinch of salt, almond extract, and the sugar gradually and continue beating until the mixture is very light. Add potato flour unsifted, then fold in the whites of the eggs which have been beaten to a stiff froth. The baking-powder goes in last and must be mixed in very carefully.

Always Had Headaches

LIVER WAS TORPID AND BILIOUS SPELLS BROUGHT SICK HEADACHES—LOST MUCH TIME, BUT IS NOW COMPLETELY CURED

Here is convincing evidence that however much you may suffer from liver trouble and consequent biliousness there is cure in the use of Dr. Chase's Kidney-Liver Pills.

Overeating is the most common cause of sluggish liver action. You lose your appetite, have distressing bilious spells, usually accompanied by headache and vomiting, the bowels become irregular, constipation and looseness alternating, digestion is upset and you get irritable and down hearted.

No treatment so quickly awakens the action of the liver and bowels as Dr. Chase's Kidney-Liver Pills. For this reason this medicine is wonderfully popular and has enormous sales.

Mr. Charles R. Tait, Newtown, N.B., writes: "I was nearly always troubled with headaches, and would often have to stop work for a day or two. I lost many a night's sleep every month with bilious sick headaches, and although I tried doctor's medicines, and also many other patent medicines, it was without success. When I had these headaches I would vomit, and could keep nothing on my stomach.

"I purchased a box of Dr. Chase's Kidney-Liver Pills from G. M. Fairwether, druggist, of Sussex N.B., and after taking one box I was so much relieved that I continued to take them until now I am completely cured. My advice to anyone suffering from sick headaches is to try Dr. Chase's Kidney-Liver Pills and be completely cured."

Mr. A. S. Mace, J. P., endorses the above statement, and says:—"This is to certify that I am personally acquainted with Charles R. Tait, and believe his statement in every way to be true and correct."

Dr. Chase's Kidney-Liver Pills, one pill a dose, 25 cents a box, all dealers or Edmanson, Bates & Co., Limited, Toronto. Substitutes will only disappoint. In sist on getting what you ask for.

Pour into a greased pan and bake in a modern over from 30 to 40 minutes. If you do not like almond flavoring, add the rind and juice of one-half lemon instead.

HOW TO MAKE YOUR BABY MORE PERFECT

Let us begin with the mouth. If it is habitually held open this will count against the baby. A baby will hold his mouth open if his nose is stopped up so he cannot breathe easily through it. Obstruction of the nose may be due to adenoids, large tonsils, lack of cleanliness or malformation of the bony parts of the nose itself.

To remedy this defect first see that you properly clean the nose daily. A young baby cannot blow his nose, so it must be cleaned out for him as part of the regular morning toilet, and again at bedtime if there is any difficulty in breathing. Make a small, soft cotton swab by twisting a little absorbent cotton on the end of a wooden toothpick, dip this into boiled water, olive oil or a little liquid albolene, and very gently clean each side of the nose. Do not use force, atomizers, etc., as substances are often forced into the tubes leading into the ears, and ear complications are thereby set up!

Older children should be taught to blow the nose thoroughly as part of the morning toilet, and again several times daily to keep the passages clear. Adenoids, large tonsils or malformations of the nose or mouth will have to be corrected by a physician.

Abnormal gums will count against the baby. If there are little white specks on the gums this may mean thrush or sprue and is due to lack of cleanliness, sucking a pacifier or to a run-down condition. To correct this be scrupulously clean about everything connected with the baby's mouth and nipples, and do not allow persons to "feel for teeth."

If the baby is not gaining well, or is anaemic or run down generally, find out the reason. Have the breast milk tested or the bottle formula changed, as the case may be.

Never roughly wash out a baby's mouth, as you will injure the delicate mucous membrane if you do, but take a small piece of absorbent cotton and twist it about your little finger or a wooden toothpick and dip this into a solution of one cupful etaoindzsoehIa solution of bicarbonate of soda (one teaspoonful of soda to one cupful of boiled water) and very gently wash the ums and inside of the mouth and cheeks wherever the little white specks are seen. This may be done every hour or two until the white specks disappear.

If the gums are very much inflamed and spongy and bleed easily it may mean a condition called "scurvy," especially if it is accompanied by painful legs; when the diapers are changed the baby may scream as the legs are handled. This often comes from lack of fresh food. In such cases give the baby row, certified milk, properly modified ,and also orange juice and beef juice several times daily.

Coated tongue and bad breath will count very much against the baby. Constipation, indigestion and catarrh may all cause coated tongue. Orange juice, prune juice, or oatmeal gruel with some form of malt sugar in the formula usually relieves constipation, or a teaspoonful of olive oil daily may be tried and training to regular habits at once started.

Indigestion may be relieved by castor oil, water to drink between meals or barley water just before a meal in case of a breast-fed baby. If bottle-fed, the formula should be changed to suit the special baby until digestion is no longer present and the tongue clears off.

Catarrh in a baby is usually caused by adenoids or large tonsils and these must be treated by a physician. If any teeth are present they must be kept very clean or bad breath will result in any case.

Deformity caused by pacifier or thumb sucking will score against the baby. To correct this stop the bad habit at once. I will tell you how to do this if you will write to me.

Delayed teething may count against the baby too. If you are feeding him correctly this is all you can do; but if not, then send for formulas or diet lists. Decayed, discolored or irregular teeth are all abnormal points. If decayed a dentist must attend to them; even the first set of baby teeth should be filled when necessary. If they are discolored, often a little powdered pumic stone, moistened and then rubbed on the discolored spots with a piece of cotton, will remove the stains.

Clean to handle. Sold by all Druggists, Grocers and General Stores.

FLEET FOOT

comes as a welcome comfort as well as a summer economy to the farmer, his wife, his son and daughter.

FLEET FOOT SHOES will make farm work easier because they are light and springy, and so staunch that they stand up to any farm work.

Their sturdy wear and low price make them the most economical shoes you can put on this summer, for you can have two or three pairs of FLEET FOOT for the price of one pair of leather shoes.

None genuine without the name FLEET FOOT stamped on the sole. Look for it.

The best Shoe Stores sell FLEET FOOT

3

In Making Seedless Jam of blackberries, a great saving may be effected by passing the berries, which have been previously cooked soft, through an ordinary rotary flour sifter. In this way, with much less work and without staining the hands, every particle of the pulp can be separated from the seeds.

By Using Both Parts of Your Double Boiler while cooking a cereal you can save fuel. For instance, while cooking your dinner put beets in the lower part and oatmeal in the upper, thus cooking both with but one light.

Fruit Jars Bought by the Dozen come in heavy corrugated-paper boxes. Instead of tearing open the top at the joints, cut around three sides with a knife and you have a lid hinged on one side. As the jars are filled place them in this box, where they will be in the dark and protected to some extent from freezing. As they are emptied wash and put the lid back on again an return to the box bottom upward. A glance into the case then shows how many jars of fruit remain. When all are empty there are one dozen jars ready for storage until next season.

To Save Sugar when making jam or marmalade, add one cupful of apples, cooked fine, to one quart of fruit, and the jam will thicken with less sugar and less boiling and retain the flavor of the fruit better.

A Very Useful Contribution to the boy going away would be several pillow slips made of khaki cloth or denim, eighteen inches square, the open ends hemmed and finished with snap fasteners sewed on at two-inch intervals. These can be carried flat, taking up no room at all and filled with straw or newspapers at each place he stops.

MARKETS.

MONTREAL

Dairy Produce Trade

The receipts of butter today were 146 packages, as compared with 140 for the same day last week, and 86 for the corresponding date a year ago. There was no important change in the condition of the market to-day, prices being steady, with a fair amount of business passing, there being still some demand for round lots from local buyers for storing purposes for future requirements, and it is also reported that sales are being made in other directions. A fair trade in a wholesale jobbing way was done and prices were unchanged, with sales of finest creamery at 46c per lb. in solid packages, and at 47c in 1-lb. blocks. Oleomargarine is steady with a fair demand for small lots for the season at 31c to 32c per lb.

We quote wholesale prices as follows:

Finest creamery.....43¾c to 44c
Fine creamery.....43¼c to 43½c
Finest dairy.....38½c to 39c
Fine dairy.....37c to 37½c

The receipts of cheese today were 11,048 boxes, as against 6,443 for the same day last week, and 6,003 for the corresponding date a year ago. At the meeting of the Peterboro board today 1,743 boxes of cheese were offered, for which there was a good demand, and all sold at 22¼c per lb. f.o.b. The make in that district for the first half an second half of July was also offered and sold at the same price, and the board adjourned for five weeks. The local trade in small cheese for home consumption was steady and sales of 20-lb. cheese and twins were made at 22¼c to 22½c per lb.

The Dairy Produce Commission is paying the following prices:

No. 1 cheese.....38c
No. 2 cheese.....22½c
No. 3 cheese.....22c

Country Produce

There was no important change in the condition of the market for eggs today, prices being firmly maintained with a good steady demand for small lots, and an active trade was done in a wholesale jobbing way. The receipts today were 1,498 cases, as compared with 634 for the same day last week, and 761 for the corresponding date a year ago.

We quote wholesale jobbing prices as follows:

Seected new laid eggs..... 50c
No. 1 stock.....46c
No. 2 stock.....41c to 42c

An easy feeling prevails in the market for potatoes on account of the more liberal supplies coming forward and the prospects are that prices will go lower in the near future, but there was no actual change today. The demand continues fairly good for small lots to meet immediate wants and sales of No. 1 Red Stars in a wholesale jobbing way were made at $7.25 per barrel, and No. 2 at $5.75 ex store, while old crop Quebec white potatoes sold at $2.65 per bag of 80 lbs. ex store.

The condition of the market for maple product was unchanged, prices being firmly maintained on account of the limited supplies now available. The demand for maple syrup was slow and in a wholesale jobbing way prices were quoted at $1.90 to $2 per gallon in wood, and in one-gallon tins at $2.10 to $2.25. There is a fair enquiry for maple sugar for shipment to the United States at 22c per lb. f. o. b. country points, and at 23c per lb on. spot

The Local Grain Market

A feature of the grain trade today was the decidedly strong feeling in the market for Manitoba barley, and prices scored an advance of 6c to 8c per bushel, which was attributed to the increased demand for supplies and the small offerings, and sales of some fair-sized lots of rejected, feed and sample barley were made on spot at $1.38 per bushel for the two former grades, ex-track here, and at the close of the market sellers in the West were asking equivalent to $1.41. In sympathy with the continued strength in the Winnipeg option market for oats a stronger feeling prevailed in the local market for cash oats, and prices were marked up 1c per bushel. There was no improvement in the demand, and business was quiet, with car lots of No. 2 Canadian western quoted at $1.02, No. 3 C. W. at 99c, extra No. 1 feed at 99c, No. 1 feed at 96c, and No. 2 feed at 93c per bushel, ex-store. According to advices from Chicago there has been a large export trade in oats of late and shipments of 1,000,000 bushels have been made within the past week, mainly via lake to Georgian Bay ports. The local market for American yellow corn was weaker and prices for this grade were reduced 5c per bushel to $1.85, but sample grades were steady at from $1.32 to $1.67½ per bushel, ex-store.

The Local Flour Market

A stronger feeling has developed in the market for rye flour, and prices for American grades in car lots have advanced $1 per barrel to $12.60 per barrel, in bags, ex-track. This is attributed to the increasing scarcity of the raw material, and the fact that prices of late have scored advances amounting to 23c per bushel. In sympathy with the above, the small offerings on spot of all grades of rye flour and the good demand for broken lots, prices today weer marked up 50c per barrel, with sales at $14 to $14.50 per barrel in bags. A stronger feeling has prevailed in the market for barley flour and prices are 50c per barrel higher, with a good demand at $12.50 to $13 per barrel in bags. The enquiry for oat flour is large, but on account o fthe fact that there is very little available on spot as yet, the volume of business is checked, and prices are firm at $12.80. Buckwheat flour is selling at $14.50, and corn flour at $12 per barrel in bags, while rice flour is also moving fairly well at $8.75 per 100 lbs., put up in 220-lb. sacks. There was quite an active demand for winter wheat flour today, and all offerings met with a ready sale at $11.40, per barrel in new cotton bags, and at $11.10 in second-hand jute bags, ex-store. There was no change in the marekt for spring wheat flour, for which the demand was steady, and sales of car lots for city account were made at $11.05 per barrel in bags, delivered, and car lots for shipment to country points were quoted at $10.95, f.o.b. Montreal.

Millfeed and Rolled Oats

There were no new developments in the market for millfeed, prices for all lines being firm, with a good steady demand for all offerings, and sales of feed cornmeal were made at $68, pure barley feed at $61, mixed moullie at $51, shorts at $40, and bran at $35 per ton, including bags, delivered. There was much better demand for broken lots of rolled oats for both local and country account, and the market was active, with a firm undertone. Sales of standard grades were made at $5.20 to $5.30 per bag of 90 lbs., delivered. A good business continues to be done in corn-meal and the tone of the market is firm, with sales of Golden grade at $6.25 to $6.40, and bolted grade at $4.50 to $4.75 per bag, delivered.

SUNFLOWER SILAGE

Experiments with sunflowers to determine their suitability for silage are being conducted in the western United States by the Bureau of Plant Industry, in co-operation with state experiment stations. There are indications that this crop may be specially useful in regious where the growing season is too cool for the production of large yields of silage corn. The experiments were begun in 1917 at Huntley, Montana, and Scottsbluff, Nebraska, and thefirst year's results led the investigators to extend the work to other points this year.

In 1917 the yields of sunflower silage exceeded those of corn silage in the same fields from 5$ to 100 per cent. Yields of more than 20 tons per acre were obtained under irrigation. Preliminary feeding tests have indicated that the sunflower silage may be substituted satisfactorily for corn silage, but directly comparable results have not yet been obtained in sufficient volume to justify a full statement as to the comparative values of the two feeds.

ARRANGING WINTER QUARTERS FOR THE SOW

Several factors should be considered when arranging winter quarters for the sow, namely,—dryness, ventilation, draughts, light, warmth and exercise.

Dryness is desirable at all times, but especially so in winter. Damp pens and moisture laden air are conducive to rheumatism, colds and bronchitis and tend towards the general lowering of the sow's vitality. Good ventilation not only supplies fresh air, but also helps to reduce the moisture. Draughts are dangerous, resulting in colds and kindred diseases. An abundance of light is an important requirment since it has a great influence in promoting good health. Warmth is not absolutely essential. Hogs can stand a great deal of cold provided they are in dry quarters and not exposed to draughts. Exercise is of great importance, being conducive to general vigor and health and tending to keep the sow's feet and legs free from various troubles.

There are several possibilities in solving the housing problem. At Macdonald College portable cabins have been used with success. These cabins are constructed with air-tight walls and are banked around the bottom. A ventilator at the apex of the roof removes all bad air. A small door is always open, the cabin being placed so that the door is facing South. Two or more sows, depending on size, are allotted to each cabin. Feed is supplied at some distance from the pen so that the sows are forced to take a certain amount of exercise.

Probably the most ideal method of wintering a sow is to give her the run of a barnyard in which there is a straw pile or a pile of horse manure. She will be certain to take sufficient exercise under these conditions. A portable cabin may be placed in one corner of the yard to serve as a sleeping pen. Other arrangements may be made to provide sleeping quarters depending on the location of hog pens and other buildings. In any case the pen should be free from draughts, dry, and well supplied with dry bedding. It is well also to bear in mind that a number of sows running together will do better and be more contented than if left singly in small pens.

A. E. MacL.

A dairy bull differs from the beef bull in the purpose for which he has been bred. The aim of the breeders of dairy cattle has been to increase the production of milk and butterfat among the individuals of the various breeds. To obtain this, the form or type of the animal had to be changed and made to correspond to the work the animal had to do. The reason why we have the dairy type so well established is because we have found more profitable milk production to accompany this type.—Fred W. Merrill.

Ne perfectly successful method of absolutely freeing cows of the germs of contagious abortion has yet been discovered. "Disinfecting cows" simply means the daily or frequent flushing out of the vagina with lukewarm water containing 30 grains of permanganate of potash to the gallon or some other solution preferred by the veterinarian who may also properly cleanse and disinfect the womb just after an abortion.

Two Cents a Word.

This department is one of the most valuable in the MARITIME FARMER. At a cost of only 2 cents a word, you can advertise anything you wish to buy, sell or exchange. The aderess must be counted as part of the advertisement and each initial or a number counts as one word. Cash must accompany each order and advertisement must have address on. as we cannot forward replies sent to this office. Copy must be received not later than Friday before the date of issue which will always be found on the editorial page of the proceeding issle. No black faced type or display of any kind will be allowed under this head, thus making a small add as noticeable as a large one. The rate for this column is 2 cents a word, each insertion. MARITIME FARMER, Sussex N. B.

HANTSPORT, N. S.

HORSE PASTURE SAVES LABOR

The saving in labor is one of the prominent advantages this year of a convenient pasture for horses. Where the horses can be turned out at night in a small pasture adjoining the barn no time is lost going after them in the morning. The horses keep cleaner on pasture than in the stable, and there is no bedding to be hauled in and very little manure to haul out. If water is in the pasture the horses drink during the night, so there is less time spent waiting for them to drink in the morning.

Every few minutes saved in a day count up to worth-while totals this year. The time-saving may easily over-balance any detrimental effect of the pasture in making the horses soft. By this time grass is hard enough to be more suitable than in early spring. The nights are beginning to get hot, and this is an additional reason for getting the horses out of close, stuffy stables as much as possible.

Fairbanks
Wagon Scales

are the practical heavy load scale for the farm as well as for contractors, builders, hay and grain dealers or coal merchants. Fairbanks Wagon Scales are simple, accurate and fill every weighing requirement in

Capacities 5 and 10 Tons

Every Fairbanks Wagon Scale may be fitted with a Compound or Columbia Grain Beam, adaptable to graduations and standards required by the purchaser. Platforms are of steel frame construction and vary from 8 x 14 ft. to 7 ft. 11 in. x 22 ft.

Fairbanks Pitless Wagon Scales

are the accurate scales for use where a pit is undesirable. Height of scale nine inches. This is an ideal outfit for farm, contracting and quarry use. Capacity 5 tons. All prices are exclusive of timber and foundations. Write our nearest branch for full particulars.

DRYING—THE EASIEST WAY TO SAVE FOOD

(Continued from page 645)

storeroom. To avoid mice and their depredations, tie the boxes or paper bags to a long wire and hang the wire from a rafter. If you have jars, the moisture problem does not exist and they can be placed anywhere. But beware of stringing up bags with ordinary twine. My first year of drying I was a novice in the ways of mice and I tied up a very nice lot of pop-corn in the old-fashioned way that is so picturesque, knotted on twine so that it hung in bunches. It looked very well and evidently the mice admired it, for they shinned down my twine and got a good feast before I discovered the fact. Use wire; mice do not seem abie to walk that.

To prepare dried foods wash them first. I prefer to pour boiling-hot water over them and wash them quickly. Then I soak them for at least eight hours, preferably over night, as that gives a twelve hour soak, and then cook in the same water in which they are soaked. This helps to retain the flavor. The one exception to this rule is beans. They taste better if the first water is poured off, although young, tender string-beans do not always need a second water.

BERNARD FRICTION PULLEY

THE PULLEY WITH A REPUTATION

When buying your engine, insist on having same equipped with a reliable, powerful and simple friction pulley. Specify Bernard's and satisfaction. It is the best at a lower price.

Made in Canada by

THE A. BERNARD INDUSTRIAL CO.,
FORTIERVILLE, QUE.

Corn, which is one of the most difficult vegetables to can, dries easily, To get a good flavor, take young, tender corn and boil in salted water on the cob (with silk and husk removed) for fully five minutes. Cut the corn from the cob and put it on racks or into roasting or frying pans. A layer of an inch and a half seems to dry all right if it is stirred occasionally. Stand the corn in pans in the oven with the door open. The oven need not be very hot, not over 200 degrees. A sour smell will soon fill the room. Wait until this odor is practically gone and then remove the corn, spread on racks or on a sheet, and dry in the sun, taking it in at night and keeping it out from three days to a week. In 1916 I had a lot of extra corn in the garden which I had no time to can. I picked and sold four hundred ears and then found I had three hundred of what I call "nubbins"—small ears that are not salable. I dried these by this method and I am still using the dried corn. All that I have done to it meanwhile is to give it an annual reheating in the oven.

Salting Down Vegetables

Several of my neighbors prefer salted vegetables to any other kind. These have the advantage of ease in preparing. In fact they are easier than dried vegetables and they taste differently from fresh, dried or canned vegetables, giving a new flavor to add to the diet. I do not mean by this fermented salting, such as is done when cabbage becomes sauerkraut, but plain dry salting without fermentation. Beans lend themeslves easily to this form of food preservation. In two hours one year I packed more string and wax beans than we could use in a Winter. The beans are gathered w,ashed and cut into inch long pieces. For my salting I purchased an empty lard bucket, washed and sunned it well and then packed the beans and salt in layers, using 1 pound of salt to every 4 pounds of beans. The salt should be sprinkled between inch layers of beans. When the keg was nearly full I covered it with a little extra salt and a clean white cloth which hung well over the edges. Then I made the original lid of the lard bucket small enough to sink into the bucket about half way and put it on the cloth. On top of the lid I laid a large stone. I did nothing more and the beans kept all winter. But I am told by the scientists that after twenty-four hours I should have raised the lid and weight and have found brine on the surface which I should have covered with melted paraffin. This prevents the ntrance of air and consequent mold. I am going to do this with my next salted vegetables, for some corn I salted did mold and although it did not spoil much of the corn I might have kept it all.

To prepare corn for salting, remove the husks and silk and boil on the cob—10 minutes if it is young corn, 20minutes if it is old. Cut off the cob and pack in the same way as the beans, using 1 pound of salt to 4 pounds of corn. If you do not want anything as large as a lard-keg, an empty candy bucket, purchased for five cents from your grocer, is a good container, or any crock which is porous. The top should be covered with melted paraffin after the corn is covered with brine and there is no bubbles. If a brine does not cover the corn at the end of 24 hours, add a brine of 2 parts salt to 1 part water and when this stops bubbling pour in the paraffin.

Peas, dandelion, beet-tops, spinach, chard, kale and green peas may be salted in this way. My salted corn had an odd flavor much like lye hominy. It was odd but palatable, and we all ate it. Salted vegetables need soaking long enough to remove any surplus salt and they can be cooked just as fresh ones.

There is one other discovery I made last year which I should like to pass on to those of my readers who are gardeners. One of the easiest vegetables to dry is the Lima bean, which can be dried right on the poles where it grows. I usually heat the beans in the oven after collecting them as a protection against insects or there eggs which may be there invisible.

Certainly with every particle of food needed, drying is a method of preservation worthy of attention. Many a city woman or small-town woman could buy up her green grocer's oversupply in the evening, prepart it, put it on her drier in her oven (with the pilot-light anad the door open) and go out secure in the fact that the product would take care of itself. Not every one has energy enough to can a surplus in the evening and it is just this wasted surplus that sends prices shooting up in the winter. The woman who ha her own garden can make use of her daily surplus in this way, drying it in the oven in racks by night and in the sun next day.

Make Your Fence Posts Last 20 Years

by using

Barrett's Carbosota
Grade-One Liquid
Creosote Oil

Government tests have proved that soft woods treated with pure, high-grade creosote oil have greater durability than untreated hardwoods.

Barrett's Carbosota is a strictly pure creosote oil of the finest quality. It has marvelous penetrative and preservative powers. It more than doubles the life of all kinds of posts, fencing, sills, and other outdoor lumber. It resists dry- and wet-rot and the attacks of all kinds of fungi and insects. It is very easy to apply, either by the brush treatment or by a simple open-tank method.

Get a can today and prove it for yourself.

Insist that your dealer furnishes Barrett Brands.

Twice as easy as walking-Three times as fast

longings. It makes life worth living, and goes a long way to raise the standard of country life.

The Art of Fixing Up

Just before the blistering heat of June and July sun, a little paint given to the repaired building will add a new charm to the attractiveness of the farm. It also adds far more value than the initial expense of the work.

Nature has given the farmer the means of decorating his home with trees, plants and flowers, but art is called in to give the finishing touches, and painting is not the least of the artful efforts. Trees and flowers are out of place where they environ, lean-to and tumble down buildings, but this combination is seldom seen, for the farmer who has no interest in beautifying his home has little interest in either paint or flowers. This is not a time when the culture of flowers can be ardently advocated, but it is not out of place to call attention to the painting of sunburned buildings. There is utility, economy and production in the procedure.

True, it takes time and time is precious in Springtime, but have the will and a way will be found to execute the work.

A dollar spent in paint will save nine dollars in boards, for lumber is going up in price by leaps and bounds. After the war, we hear it said that prices will fall. This may be true of some things, but not so of lumber and steel. Hundreds of millions of dollars worth of lumber and steel are annually being swallowed up and destroyed in war's carnage, and the supply of raw material in these lines is not by any means inexhaustible.

Buy a can or two of paint and utilize every spare moment to get it spread on the home, the barns, their doors or windows, or wherever required, and you will find in the near future that you have been saving money and conserving power for your industry. Do not slight the idea that real wastefulness results from lack of the use of paint. A saving of material is so much added to the profits and painting increases the profits by prolonging the life of the material.

How to apply the Paint.

To make a good job, paint should not be used in damp weather, nor on wet wood work. When the wood is dry it absorbs more of the paint; the paint penetrates deeper into the wood and therefore gets a firmer hold on it and si more effective. Use a brush three or four inches wide for large surface painting. Begin at the top and paint downward. Keep the paint a uniform color and consistency by stirring occasionally. Give the first coat sufficient time in which to dry before applying the second coat.

On the quality of the paint and the quality of the work depends the number of years it will last. Good lead paint properly put on and given three coats will last for seven years. The side of the building exposed to the rays of the sun requires to be painted more often than the sheltered side. Economically, there is no more important factor around the farm than that of paint. The springtime keynote is paint, and the last refrain is paint. Catch it up and let it resound through the land.

IMPERIAL SERVICE

If you are in doubt about the proper lubricant, *ask the Imperial Oil man.* He will give you courteous attention and sound advice on your lubrication problems. That is part of Imperial Service.

CALL AT HEADQUARTERS

WHEN you add a new machine to your farm equipment—a tractor, a stationary engine, a drill, a thresher—no matter what the machine, you need dependable lubrication advice. You want to be sure the oils you use will maintain your machine in constant service and give it long life. Look to us for the answer to your problem. We know the oil you need for each particular purpose. We know the lubrication requirements of every farm machine. Our chief interest is to do away with lubrication troubles, to make sure that you are using the correct lubricants.

All our oils are supplied in steel barrels and half-barrels—convenient, economical. No waste. You use every drop you pay for and you know every drop is uniform and clean.

WATER FOR THE WORKING HORSES IS IMPORTANT

A surprising difference in heat resistance could be noted among farm teams during the recent very hot days. On some farms the horses worked right along without let-up; on others they appeared fagged and they evidently suffered from the heat. One of the conditions commonly present where the teams worked well was adequate provision for watering the horses. The water was pure, cool and plentiful. Generally it was offered frequently. In many cases the horses had free access to water during the night.

When weather is very hot a horse at work sweats out of his body a great quantity of water during the day. It is impossible to drink enough at the usual four waterings a day to fully replenish the water content of the body tissues and organs. As the hot day draws to a close the hard-working horse gets more and more in need of water throughout the body. He craves it. When he comes in at night, tired and thirsty, his capacity for holding water limits the amount that he can drink long before a balance between water and solids in the body is re-established. Perhaps the driver drags the thirsty horse away from the trough before he is through drinking because he fears too much water will be taken in and a case of colic be the result. Another chance to drink is planned, but perhaps forgotten. More frequently the horse is taken away from the water tank too soon because his pause in drinking to catch his breath and allow the water the pass through his stomach is mistaken for the signal that no more water is wanted.

In well regulated city stables this difficulty is overcome by watering the horses again after supper. This is seldom done in the country unless the horses are turned out for the night. Really it is better for the horses to turn them out where they can drink at will during the night. They are wonderfully refreshed by this practice just as men are refreshened by the long draughts of water that are taken several times after quitting the field on a very hot day, winding up with two or three glasses of water just before going to bed. Even where horses are not pastured at night they derive great benefit from resting and eating their hay in the barn lot with access to water. In a lot not too small there is not much danger of tired work horses injuring each other in summer. Many outfits spend the nights thus during early summer, and after about this time of year or a little earlier, when the grass gets more mature, they are turned on to pasture at night. The plan works well.

In very hot weather, particularly at harvest time, some of the most efficient farmers haul a barrel or two of water to the field and the horses are watered once or twice during each half day. Those who follow this plan assert that the horses will then do far more work in hot weather than if watered only morning, noon and night. Some accounts are related of marvellous endurance and big days' work accomplished under excessive heat by horses that had water given them frequently during the day. The only objection to it is the inconvenience. But then it is inconvenient for any one or any horse to work in the hottest days, so we might as well accept as desirable any means of accomplishing results and safeguarding the health of teams.

It is not thirst that allows a horse to be overcome with heat. It is a weakened condition of the system. Too ittle water is a common contributing cause to this decrease in vitality. A horse, like a man, craves water more than anything else in hot weather, and that of itself should be sufficient proof of the importance of plenty of pure fresh water.

Recruiting Officer of Crack Regiment—So you wish to join the corps, do you? Had any military experience?

FOR SALE!

Present offering, one Bull Calf.

P. R. L. FAIRWEATHER,
Rothesay - - - N. B.

Lawndale Stock Farm
Jerseys and Shorthorns (Pure Bred)

JERSEYS

Young Bull, solid color, dropped Sept. 1st, 17 Out of R.O.P. dam and by a noted sire—combining the blood of Golden Lad, Tormentor and Flying Fox.

SHORTHORN:—

2 Young Bulls—One dropped Jan. 22, 1918, of the purely milking type, out of a great milking dam and by a Champion sire in his class.

The other dropped April 2, 1918. Splendid specimens of beef type. Out of very large and blocky dam and heavy sire.

Both these calves are mostly red in color and in show condition.

I. M. LOVITT, M.D.,
Yarmouth North, - Nova Scotia

Maple Green Farm Holsteins

Just now we are offering some fresh calved cows and some due to freshen shortly, also yearling heifers and heifer calves, all with official records or from official record dams. Remember this is the only herd in Eastern Canada which owns two Jr. 3 year olds with official records of 25.05 and 26.54 lbs. butter in 7 days.

Herd sires in service, "Maple Grove Mercena Mercedes," No. 11727, the sire of our 26.54 lb. Jr. 3 year old and who so far has not a tested daughter testing under 4%. Our Jr. herd sire, "Homestead Hengerweld Rooker," No. 20652, three-quarter brother to our 25.05 lb. Jr. 3 year old.

For particulars write

R. L. HICKS
Dalhousie Jct., - - N. B.

ROSEWARNE
S.C. White Leghorns

I am now booking orders for baby chicks and hatching eggs from my well known bred-to-lay strain. Chicks will be very scarce this spring, and there will be a wild scramble later on for supplies, so get your order in early and pick your date.

My cockerels and pullets, out of same matings as day-old chicks were sold from last season, swept the board at Halifax.

Send for prices and mating list.

ERNEST CRAZE
Port Williams, - - N. S.

GLENRANE STOCK FARM

We are offering some very fine pure bred registered calves from 2 weeks to 8 months old These calves are sired by "Homestead Hengerweld Rooker" ¾ brother to a 26 lb. jr. 3 yr. old. They will be sold reasonably if taken at once. We also have several litters of very fine York pigs.

ROBERT C. HICKS,
West Bathurst, - - - N. B.

Chester White Pigs for Sale

Book your orders now for Chester White Pigs from four weeks upward. Pairs furnished that are not akin.

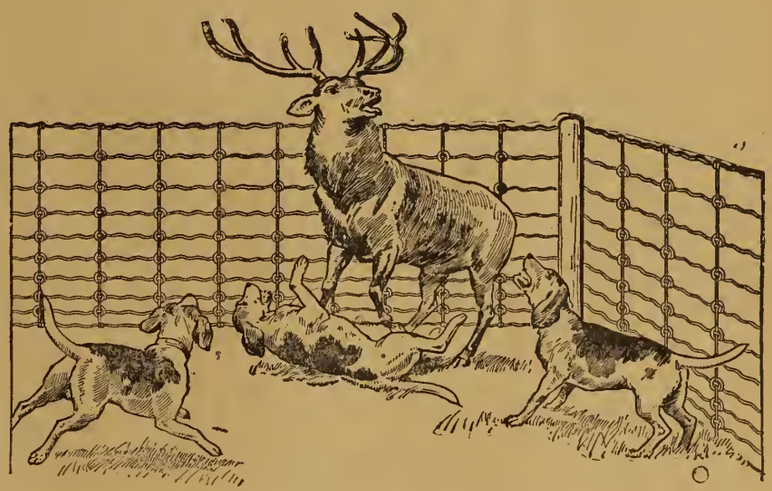
MARITIME WIRE FENCES

are made entirely from extra heavy hard drawn No. 9 steel wire. This is evenly coated with a superior peel-proof galvanize. The strands and the stays are firmly held at every join by our special never-slip lock. This knits the whole fence into one resistant fabric. There are no loose stays, no faulty locks, no spots ungalvanized. Maritime Wire Fence has "No Weak Link." It stands the tests of man, and beast, and cold, and time. It retains its shape and sightly appearance, even after years of hard service.



—HELD AT BAY—

This is because reliable materials are used throughout, and these materials are made into fence by men who know their business. Isn't there a great deal of satisfaction and pleasure in owning a fence that needs no repairing; that stays taut and straight without sagging and buckling?

MARITIME WIRE FENCE

Don't buy fence of any quality or quantity until you have thoroughly posted yourself on what Maritime Wire Fence has to offer you. It might be well to write for our Fence Book and Price List, while you are thinking about it.

ICE-CREAM MAKING ON THE FARM

Some people like homemade ice cream better than that commercially manufactured. Homemade ice ceram is very easily made, and is inexpensive. An ice cream freezer may be bought in different sizes at a small cost. Ice would be hard for most farmers to get, but it can easily be brought out by friends in town, and a delicious, refreshing product could be quickly made after a hard day's work.

A good formula to use for one gallon of frozen cream is one-half cup of gelatin dissolved in two pints of hot milk. Have two eggs and 1½ cups of sugar beaten together and then add this to the hot milk and gelatin. Pour this into the freezer can and fill up until it is two-thirds full with a mixture of milk and cream or all cream. The more cream is used the richer and the better body the frozen cream will have. If all cream is used the gelatin can be omitted if desired. Flavoring extract may be added to suit the taste. The ice should be broken up fine and one part of salt added to eight parts of ice and thoroughly mixed. More salt may be used if quick freezing is desired. The ice and salt is placed in the freezer around the can and the turning process began. It should not be turned too fast, as it will give too much swell in the early part of freezing, and this will fall down, leaving a poor, soggy body. It should not be turned too slow, or a nice velvety body of cream will not be secured. The freezing process will ordinarily last 10 to 15 minutes, after which the dash should be immediately removed and the cream packed until it gets real solid. The dash may be left in, but it is hard to dish the cream with it in.

Another simpler method of making ice cream can be used where the richness of the cream is known. Where cream is sold one will know approximately the percentage of fat. Few farmers have a Babcock testing outfit, but the fat could easily be determined if one was in possession. In this case for one gallon of 20 per cent cream add 1.6 pounds of sugar and .8 of an ounce of vanilla or other flavoring extract. Eight-tenths of an ounce of gelatin may be used for a stabilizer, but a very

Butter Parchment at Farmer Office

good body can be secured without it, and it saves heating up a part of the cream to dissolve the gelatin. Where the cream is richer than 20 per cent., milk may be added to dilute it. Ices and sherbets can also be made very easily on the farm. They are harder to keep, and must have better packing than ice cream.

BAD TASTE IN BUTTER

Will you please tell me what is the matter with my butter in hot weather? It is all right until along about dog days, and then it ets such a bad taste that nobody can eat it. It only lasts till the dog days are over. We always cool the cream. Please tell me what I can do to stop that bad taste. L. K.

There are a number of causes for the bad taste which you note in your butter during the hot, sultry days in August. First, it may be possible that it is due to some feed which the cows get hold of. This is the least probable cause, however. It may be due to the method used in separating the cream from the milk, to the temperature to which the cream is cooled and held, or to the age of the cream at time of churning. If you use the shallow pan system of raising cream, it is almost impossible to make a good quality butter in hot weather, as the cream usually becomes sour by the time it can be skimmed. If you use the separator, each lot of cream should be cooled to 50 degrees or below in ice water immediately after separation. The cream should not be over four days old at the time of churning. The main thing is to keep the cream absolutely sweet until the night before it is to be churned. You can then allow it to sour slightly by placing it at room temperature over night. Do not let it get too sour.

Attractive Fence Prices

for Immediate Delivery

Guarantee—We guarantee our fence to be made throughout from the best Galvanized Hard Steel Wire, full Government gauge, and to be the most perfectly woven fence on the market. We absolutely guarantee every bale of Sarnia Fence to stretch with an even tension all line wires.

Present indications are that by next spring it will be impossible to buy fence at any price. We have only a limited tonnage to offer at these prices. After our present contract has expired prices will be advanced materially. Think what a saving in price and trouble you would have made had you purchased your fence for this spring, a year ago. The situation will be worse than ever before the coming spring. The tonnage which we have to offer at these prices will be sold very rapidly. Do not wait until it is too late. **MAIL YOUR ORDER TODAY.**

THE SARNIA FENCE CO., LIMITED, 814 Christina Street SARNIA, ONTARIO

Harvest Hands Wanted in New Brunswick

The Department of Agriculture for war purposes, last spring, urged Greater Production. 103,772 bushels of seed grain were imported. The farmers have responded splendidly. The acreage under crop is in excess of any previous year. Climate conditions have been favorable, crops promise well.

Every acre of crop in this Province must be properly harvested this year.

Many men have been called to the Colors.

Under the conditions the Department fears that many crops will remain in the fields unless men from our towns or industrial plants become harvesters, and are setting up labor bureaus in different sections of the Province to ascertain the farmers' labor needs and to register voluntary labor.

Every man in the towns or cities who has had farm experience should be ready to assist for a few days.

Every farmer should register his wants immediately at one of the following bureaus. A guarantee of help cannot be given by the Provincial Department of Agriculture, but when the requirements are known after a certain date, if necessary, the Dominion authorities will be appealed to.

Give name, address, railway station, number of days help required and when. Approximate wages per day. Where wages cannot be satisfactorily arranged, an appeal to the Department of Agriculture may be made for adjustment.

Every man willing to help should also be registered at one of the following places:—

St. John—William Kerr, N. B. Government Office, Prince William Street.

Fredericton—A. B. Wilmot, Dom. Immigration Office, Post Office Building.

Sussex—J. D. McKenna.

Moncton—J. H. King, Agricultural Representative.
Chatham—James Bremner, Jr.
Bathurst—Frank P. Doucet.
Andover & Perth—Dr. Dickenson.
Woodstock—A. C. Taylor, Agricultural School.
St. Stephen—W. S. Stevens.

J. F. TWEEDDALE,
Minister of Agriculture.

THE SUSSEX MANUFACTURING CO., LTD., Sussex, N. B.

WINTER RYE AS A GRAIN CROP IN NEW BRUNSWICK

(Experimental Farms Note.)

With the call for increased production of bread stuffs, there should be careful consideration among our farmers of what they can do to meet the emergency. Wheat, of course, is the most desirable grain for bread making and for supplying bran and middlings for stock feeding, but in many parts of New Brunswick this grain has not been a sure cropper, nor is it likely to be until more is learned about the prevention of diseases and other methods necessary to insure a good crop.

When the country was first settled nearly every farmer could and did raise his own wheat flour, though the yields of grain were not always satisfactory, but in later years, with the advent of a cheap flour from Western Canada, it was found much more profitable to grow other grains and buy flour. Consequently, in the central and southern parts of the province but little wheat has been grown and as these parts were large importers of oats as well as flour, oats, being the surer crop, were generally grown to the exclusion of wheat. On the Upper St. John and along the Northumberland Straits, however, wheat has been consistently doing well.

To test the adaptability of this crop to New Brunswick conditions the Experimental Station at Fredericton has been growing winter rye anad up to date, with very satisfactory results. On the 15th September, 1916, an area that had grown a soiling and silage crop of peas and oats was seeded to winter rye at the rate of about seven pecks to the acre. This started well that autumn and after dying down during the winter cams strong in the spring of 1917 and in July ripened a crop of thirty-four bushels per acre on straw from five to six feet in length. This crop was not pastured at all and the stand was rather thin.

On September 17, 1917, some of the seed of the above crop was sown at the rate of two bushels per acre upon land which had grown a crop of flax that year. This was pastured rather severely by lambs in October and November, but the crop came strong in the spring of 1918, the plants stooling freely, from five to ten good stalks coming from every plant. This crop on July 1st has reached a height of from five to six feet with good heads and gives every evidence of yielding over thirty bushels of grain per acre.

Rye flour makes a dark but a sweet and nutritious bread and at the present time is the main cereal food for millions of people in Northern Europe. From the evidence gained at the Experimental Station, Fredericton, and the experience of various farmers throughout the Province, it would seem very desirable that New Brunswick farmers who are not successful with wheat should try a piece of rye for next year. As long as the supply lasts, seed of winter rye may be obtained at the Experimental Station, Fredericton, N. B. Land from which an early crop of potatoes is taken will be very suitable or a clover sod ploughed immediately after haying and kept well cultivated will give a crop. Any kind of sod land that is fairly well drained can be fitted by ploughing as early as possible in August, harrowing thoroughly immediately and afterwards at least once a week until seeding. In most cases it would insure a better crop to spread from ten to fifteen loads of manure per acre and disc it into the soil. If only long green manure is available it might be spread on the sod and ploughed in.

BUTTER FROM 22 PER CENT CREAM

How much will a gallon of 22% cream weigh and how much butter will it make? How much butter will one hundred pounds of 22% cream make?

M. G. B.

Cream testing 22 per cent fat has a specific gravity very nearly identical with that of water. A gallon of 22 per cent cream will weigh approximately eight pounds; to be exact, 8.048. In a gallon of such cream are 1.77 pounds of butterfat.

The amount of butter which can be made from this quantity of butterfat may vary considerably. The maximum allowance of 25 per cent overrun would give a butter production of 2.21 pounds. However, two pounds of butter would more nearly represent the average quantity which, under ordinary conditions, could be secured from this amount of fat. From one hundred pounds of 22 per cent cream, average efficiency in churning would secure a little over 26 lbs. of butter.

FOR SALE!

One No. 50 Bell Ensilage Blower in perfect working order, has only been used a little. Will sell for about one-half the price of a new one. For particulars apply to

Keeping the Flock in Health

It has often been said that stomach worms have done more to reduce the number of sheep than all the predatory animals. At least such a statement can be made in compa ring the losses from all diseases with the raids. The worst of it is that these losses are within the control of the flockmaster himself, while the dogs belong to someone else.

The fault with most sheepmen is that they are not well acquainted with the commonest and most disastrous ailments. Doctor Wilson has summarized so clearly the difficulties that a man may expect in the field that he should be able to save meat, wool and sheep.

Of all the domestic animals, none are more responsive to kind treatment and hygenic surroundings than the sheep. It is equally true that none possess less resistance to disease, and when once attacked succumb more readily than do sheep. The old adage that an ounce of prevention is worth a pound of cure is truer in the maintenance of the health of the flock than in any other class of domestic animals.

The first esssential in the hygenic surroundings of the flock should be high, well drained and well ventilated quarters for both winter and summer. As long as the winter quarters are dry and free from draughts, it matters little how cold they are excepting, of course, during the lambing season. Low, damp, poorly ventilated barns predispose the animals to colds, pneumonia and kindred diseases. Once a sheep is affected with pneumonia, recovery is rare. Low, damp pastrues in the summer time lead to parasitic infestation and occasionally to blackleg, anthrax, and hemmorhagic septicemia. The latter three diseases can be successfully combatted by vaccination. Foot rot is another disease brought on by damp, filthy surroundings. Too much emphasis cannot be laid on having the winter quarters high, dry and well ventilated, and the pastures well drained. If such conditions exist the losses from parasitic diseases, pneumonia and foot rot will be reduced to a minimum, and should be very small indeed. The sheep is a native of high, dry surroudings and as such we must pattern after nature, or as in all other digressions from nature's way, pay the penalty.

Fresh Water

Important as clean, dry suroudings are, pure fresh water is equally as important. The all too common practice of allowing the flock to drink from stagnant pools in the pasture or even from a stream which drains from a pasture where sheep are kept cannot be too strongly condemned. Water from such sources is almost certain to be contaminated with the eggs of many of the various parasites affecting sheep, as well as carriers of the germs of some of the infectious diseases to which the sheep is subject. The ideal water supply comes from a well or spring where there is no possible chance for pollution with the eggs of parasites or germs of infectious diseases.

In the summer time the water should always be kept fresh and cool, not cold, however, preferably in a shaded spot, while in the winter time it is much better if it can be kept reasonably warm. It should never be ice cold. While it is true that nature has made provision so that the sheep can stand exterinal cold without harm, yet internally the animal possesses little resistance to cold in the form of frozen feeds or ice water. In the majority of cases a sheep will not drink enough cold water in the winter time to properly carry on digestion, resulting in constipation and diminished gain or in severe cases diarrhoea and death if the condition is not promptly remedied. Ice water given to pregnant ewes in some cases has been known to produce abortion.

Errors in feeding often seriously menace the health of the flock. Frozen or mouldy silage is almost sure to produce serious intestinal disorders often leading to death. Too much roughage with too little concenrtates often produces constipation or impaction of the first stomach, which if not immediately treated, ends fatally. In feeding, the animals should be kept under close observation to see that they are getting enough laxative feed in the way of silage, roots or concentrates to keep the bowels open. However, it must be remembered that too much of such feeds must not be fed, especially to pregnant ewes, or bad results will follow. The condition of the animals bowels is the best guide to follow. High priced mutton and wool, and high priced feed, not only make it profitable from a health standpoint to keep the animals in a good, thrifty condition, but from a financial one as well.

One other essential to the health of the flock is exercise. Pregnant ewes especially cannot be expected to bear strong lambs unless the yhave regular exercise during the period of pregnancy. Of course it is not advisable to have the animals out during stormy weather, but on all dry days they should have plenty of range. Many successful sheep men force their flocks to take exercise by having part of the feeding racks forty or fifty yards from the barn. While such a practice means more work, yet these men are rewarded by vigorous breeding stock and strong, healthy lambs.

Parasitic Trouble

Of all the diseases to which the sheep walls heir, none give the flock owner as much concern as those caused by parasites. In the past many sheep men have been put out of business by parasitic diseases of their flocks. In the future with more men going into the sheep business, trouble from parasites is sure to increase unless intelligent measures are taken to keep them under control. Once a flock is infested with parasites, its complete cleaning up is very difficult. The important question to answer then is can a clean flock be raised from infested breeding stock? Fortunately in the case of most parasites the answer is in the affirmative.

Let us consider some of the most important parasitess individually. Probably no disease is more widely spread among sheep than nodular disease. The life history of the parasite causing this disease is imperfectly known, yet it is certain that in most cases, at least, the infection is taken in by the sheep with the food or drinking water. It has been amply demonstrated, first by the Louisiana Experiment Station, and later by others, that by what is known as the barelot method of feeding, clean lambs can be raisced from infested ewes. Essentially this method consists of providing the lambs with food and water not contaminated by the feces of the ewes. To accomplish this, the ewes with their lambs are not allowed to run on pasture together, but are kept in a bare lot free from all vegetation. All food is fed in racks and troughs so constructed that none will drop upon the ground and become contaminated. The watering troughs are also arranged so that there is no possibility of their becoming contaminated with feces of infected sheep. After the lambs become old enough so that it is only necessary that they suckle twice a day, the lambs ca nbe kept in one pasture and their mothers in another. Of course, the pasture where the lambs are kept should be one that is positively known to be free from infection, which generally means land which has not been pastured by sheep the year previous, and is well drained. While such a plan involves considerable extra labor, yet it is time well spent as a sheep suffering from nodular disease never makes rapid gains especially in the winter time. The greatest losses from this disease occur during the winter months when the animal are on dry feed. The affected animals become unthrifty and weak. If many parasites are present, death results. Post-mortem examination reveals from one to several hundred nodules about the size of a pea or larger in the walls of the intestines caused by the parasite having buried ntself there.

The Stomach Worm

Probably the most difficult parasite which we have to combat is the stomach worm. It is a reddish-brown, thread-like worm a little over an inch in length, living chiefly in the fourth stomach. It does its harm by absorbing nutritive elements from the stomacn, by absorbing blood from the walls of the stomach, and by producing a poisonous substance which destroys the red blood cells. Numerous experiments have been conducted in an effort to find some method of pasture rotation or barelot feeding to control this paraisite, but up to the present time such methods have proven of little avail. It is known that the young larvae are taken in with the food or drinking water, and that lambs become infected at an early age by taking in the larvae as they suckle their contaminated mothers. The most pronounced symptoms are noted in lambs and yearlings. In lambs the first symptoms usually are noticeable just after weaning. At this time they gradually fall away in flesh, become weak, and if the mucuous membranes of the mouth are examined, they will be found to be pale in color; later swellings appear about the neck and brisket. Of course all infseted lambs do not succumb to the disease, the greatest loss being from lack of thrift. Once a flock is infested, it cannot be hoped to entirely rid it of the parasites. Their control can in a large measure, however, be accomplished by proper management, such as pasture rotation, and at all times plenty of pure water, and by medicinal treatment with copper sulphate, gasoline or one of the various combinations of iron, arsenis, areca nut and salt.

Another parasite of considerable importance is the lung worm. It is greyish-white in color and about an inch in length. Its life history is not completely known, yet it is known that the organism will live for a long time in moist soil, outside of the animal's body. The first symptoms noticed in the affected animals is a more or less violent cough, later difficult breathing, emaciation and debility. The cough is especially noticeable during exercise. Post-mortem examination reveals the parasites in the lungs and bronchial tubes. Until Horms and Freeborn of California discovered the chloroform treatment, little could be done to relieve the condition. The chlorform treatment has, however, proven to be very effective. The affected animals are given enough chlorform by inhalation to make them stagger. This produces enough irritation to start the animals coughing and thus expells the worms which have been partly anesthetized by the chloroform. As the animal swallows most of the parasites as they are expelled from the lungs, a saline purge should follow in two or three hours. Food and water must be so placed that it cannot become contaminated with the infective feces.. This treatment should be repeated in

Some Constitutional Diseases of the Potato

Paper Read at Conference of Agricultural Representatives in Guelph, by Paul A. Murphy, in Charge of Potato Disease Investigations, Dominion Department of Agriculture.

It is not necessary to study statistics of potato production to see that potato growig is not on a whole a very successful or profitable line of farming in Ontario. This is particularly so if one is familiar with the potato industry in other parts of the Dominion. The statistics, however, amply bear this contention out. Turning to the average yield per acre for the last ten year period we find that the highest yields are obtained in British Columbia, namely 206 bushels per acre, and that the figure drops more or less gradually as one comes east through the Prairie Provinces. The next highest yield after British Columbia is obtained in the Maritime Provinces, where it averages about 190 bushels during the same period. In Quebec the figure comes down to 140 bushels and in Ontario it reaches 123 bushels per acre, the lowest in the Dominion.

The reason for this gradual decline in yields from both coasts is probably not a simple one, but a partial explanation is not far to seek. It is known now that a number of very serious diseases are more or less widespread in Ontario grown potatoes while they are absent or present in less virulent form in those parts where the yield is high. This is known to be true in the Maritime Provinces taken as a whole, and it is also presumably true for British Columbia. It is known that these disease besgin to appear in agravated form in Western Quebec and the fact is significant that it is about here we first meet with lower yields. It might be suggested that the climatic conditions are rally responsible for the reduction in the crop. This is no doubt true, but only indirectly, as will be shown. The fact, now so well known to experimenters and many practical growers, that good seed imported from New Ontario or the Maritime Provinces at first yields just as well even in districts reputed poor potato sections as in its original home is sufficient to show that climate is not directly responsible.

The principle disease which is prevalent in many parts of Old Ontario, and which is apparently responsible more than anything else for reducing the yield of potatoes, is the Leaf Roll. Plants attacked by it are considerably dwarfed in size and of a lighter green color than normal. They are stiff and upstanding in appearance and the lower leaves in particular become thick and tough to the feel and curl up at the sides instead of being flat. They afterwards become spotted and begin to wither particularly near the tips. It should be remarked that this rolling is on the lowest leaves and it is not to be confused with curled up and limp appearance of plants suffering from drought and heat which is now so general.

Leaf Roll plants give about one-third of the normal yield. The potatoes tend to be small and they are attached close to the stem as a rule. There is no sign of the disease on the tubers. These potatoes if planted invariably give rise to a diseased crop with the same symptoms and same yielding capacity. This is the principal way in which the disease is perpetuated, but it can also spread short distances in the field from affected plants to neighboring healthy ones. The latter look normal the first year but the tubers produced by them may give rise to a crop which is largely diseased.

It also appears clearly from some experiments carried out by Dr. C. A. Zavitz at Guelph that climatic conditions induce Leaf Roll in potatoes which were previously healthy. The author has observed in importations of the same strain of potatoes which have been made year by year from New Brunswick and Northern Ontario that there is no Leaf Roll in the stock the first year they are grown at Guelph but that it then appears and increases rapidly, as shown in the following table:

Leaf Roll Record of the Same Strain of Potatoes After Being Grown:

1	year	at	Guelph.....	0%	Leaf	Roll
2	"	"	"	15%	"	"
3	"	"	"	24%	"	"
4	"	"	"	63%	"	"
6	"	"	"	89%	"	"

Another important disease which reduces the potato crop in Ontario, is Mosaic. It is recognized bythe fact that the leaves are corrugated or puckered all over and mottled with faint light green spots. It is most prevalent on Green Moutains and is most readily seen during dull, cool weather such as we had in June. Diesased plants may not be much reduced in size unless the attack is severe but they are less vigorous and less well able to withtand drought and tin-burn. The yield is not reduced to the same extent as in Leaf Roll, but it seldom exceeds two-thirds of the normal. The eating or keeping qualities of the potatos are not affected and there is no sign by which diseased tubers may be recognized.

The trouble is spread by the use of the seed from affected plants as in the case of Leaf Roll. It is not known definitely if it spreads in the field or if the climatic conditions of Ontario induce it in healthy potatoes, but both may occur. It certainly often appears in a much more agravated form in Ontario than in the Maritime Provinces for instance.

The control of the Leaf Roll, Mosaic and some similar but less comon diseases can be readily deduced from what has been said above. It consists of the periodical introduction of healthy seed from districts from which Leaf Roll at least is naturally absent. Such districts as these may be found in Northern Ontario and the Maritime Provinces. This course is being followed with success by many growers and the experiments now being conducted by the Ontario Department in every county in the Province to compare New Ontario, New Brunswick and Old Ontario seed will sow to what exten it should be extended. The Dominion Department of Agriculture is also making a comprehensive survey of Old Ontario to determine to what extent these diseases are present. This information is needed before comprehensive control measures can be suggested. The importation of healthy seed is the only course open, but fortunately it gives a perfect control of the diseases if the seed is imported sufficiently frequently. The selection of healthy plants from partly diseased crops in Old Ontario with a view to using their product for seed is not recommended.

It also follows from the fact that none of the diseases mentioned can be detected in the tubers that the only guarantee possible to the man who buys seed is a knowledge of what the growing crop looked like the previous year. The Dominion Government maintains an inspection service in the principal seed growing districts for this purpose. The crops are inspected before and after harvest and tags are supplied to growers who have potatoes fit for seed purposes to mark their stock with. This system was put in active operation for the first time last year and it is confidently believed that with the experience then gained a supply of the best possible seed will be secured which can be purchased with confidence that it is the best procurable. Where our survey work shows that much Leaf Roll and similar serious diseases are present it will be found that the planting of the certified imported seed will very largely increase potato production.

One Reason Why Insects in Search of Their Food Avoid Healthy Plants

Any treatment which increases the vigor and hastens the normal growth of corn, wheat, or other agricultural plants usually increases their power to resist or overcome the attacks of insects or disease; and it is evident that imperfect, abnormal or poorly nourished plants are more likely to suffer from such attacks than healthy plants.

It is comon observation that the chinch bug or Hessian fly may attack and almost destroy wheat that would otherwise yield 10 or 15 bushels per acre, while wheat growing on another part of the same farm or field on land naturally more productive or better fertilized, and capable of producing 30 bushels or more per acre, is not attacked or at most not noticeably injured.

Animals and Plants

It is well known that animals which are not well fed and allowed to become poor and weak are much more liable to attacks from lice or other insect diseases, or to suffer from disease; and the information is sufficient to convince any careful student that plants are subject to similar attacks under unfavorable conditions.

Just how strong, healthy plants are able to resist or overcome insect attacks, while weak plants succumb to them is not fully determined. Of course, if a plant is subsisting on what might be called a half ration, an injury to a root by the bite of an insect or a loss of sap withdrawn by a sucking insect must further weaken the plant; whereas if the root system is taking up such an abundance of plant food that there is a tendency for the plant to start new plants or shoots, as in the suckering of corn, then such a root injury may have no effect on the main stalk.

Why is it that fleas or bed bugs will attack one person and not another sleeping in the same bed? Why does poison ivy poison one person and not another. Unquestionably there are similar differences among plants.

The larvae of the Hessian fly must secure its food by attacking the plant, but if the plant is able to heal the wound before the larva can enlarge it the insect may perish. The plant may be poisoned by insects or by fungi, and it may have power to develop an anti-toxin or serum to destroy the poison, provided the plant is well-nourished. This is within the reasonable possibilities but still undetermined.

Peculiar Powers of Plants

Plants have some remarkable properties. For erample, a plant may be grown in a solution containing equal amounts of sodium and potassium, both in salts, soluble in water, but the plant will absorb the potassium and largely reject the sodium. This is known as the power of selective absorption, and that plants have this power is well established. To prove this fact one needs only to analyze either the plant or the unused portion of the solution in which the plant has grown for a time. Such an analysis regularly show that the plant takes up most of the patassium while most of the sodium remains in the solution.

When the sugar tree is tapped, a stream of sap flows from the side of the tree. But the water in this liquid was first taken from the soils. Thus, the plant has power to elevate water and to discharge it far above the surface of the ground. This, too, is a remarkable property of plant dife. It is illustrated by the drop of fluid which at times appears on the tip of the brace root of corn before it penetrates the soil.

When the legume plants are sparsely infected with the niortgen-fixing bacteria, the tubercules usually become very large, but when the points of infection are numerous, the individual tubercules usually remain small. Seemingly, hte host plant, such as alfalfa, for example, has power to feed the bacteria so abundantly at one point as to cause their rapid multiplication, in order that they, in turn, may furnish the alfalfa with more nitrogen.

Most people have seen how a tree heals a wound, as where a limb has been cut off, but I was once shown an old stump of a beech tree which was still alive years after the tree had been cut down. This stump seemed to be trying to heal itself over the top much the same as a tree heals over where a limb is removed. The stump seemed to alone, with no sprouts, but another beech tree was growing nearby, perhaps ten or fifteen feet from the stump and I have no doubt that both belonged to the one root system and that the living tree fed the stump and thus kept it alive; and because the stump still lived it had power to resist the attacks of fungi and other agencies of disease which commonly produce decay.

Life is really the great mystery. How quickly the evidence of decay appears when life is gone, whether from animal or plant; the dead calf is soon putrid anad the dead corn kernel planted in the fertile soil is soon attacked by mold.

Doctor S. A. Forbes, the well known entomologist, has suggested that one reason why insects avoid healthy plants is that the very dilute juice or sap of a succulent rapidly growing health plant may constitute a starvation diet for healthy insects; in other words, that the capacity of the insect for such juice is not sufficient to furnish it with the amount of nutrition necessary for maintenance and reproduction; and that sucking insects prefer the concentrated sap of somewhat withered plants.

Quack or "twitch" grass must be kept below ground or else dug out entirely if you expect to grow vegetables in the same field.

Pull and burn diseased flowering plants. They are of no further use and may spread much trouble.

The Common Breeds of Sheep

Their Adaptability for New Brunswick Conditions

By Thomas Hetherington, Live Stock Superintendent Dept. of Agriculture, Fredericton

We have in New Brunswick at least nine breeds of sheep some or these being adapted to our conditons more than others. These breeds may be conveniently classified as follows:

1. Long Wooled—(Cotswold), (Lincoln', (Leicester).
2. Medium — (Cheviot), (Dorset Horn).
3. Short Wooled or Down Breeds— .Oxford). (Shropshire), Hampshire). (Southdown).

The long wooled breeds enumerated above are very old English breeds and it was this blood that was used as foundation stock by the pioneers ot this province. Quantity of wool foi the coarse homespun clothing which these breeds could supply was all the justification necessary to support the pioneers choice of breed. In the main the grade and native stock now found in the province is descended from either one of the long wooled breeds as evidenced by the predominance ot white faced sheep at the present time. These three breeds the Lincoln, Leicester and Cotswold have many things in common. They are the largest sheep we have, on the average they cut the most wool, they are considered our most delicate breeds, this being especially true of the Lincoln and Leicester and as a consequence are on the whole more susceptible to disease than are some of the hardier breeds that will be mentioned later. Other features which are characteristic of the long wooled breeds is the openness of the wool, inclination to bareness on hte belly, and the coarse nature of the wool.

Due to their size these breeds demand exceptionally good pasture and careful feeding in winter. Hence the farmer with light soil, little feed and barren hillsides for pasture would do well to select a lighter breed more adapted to his conditions. Present high wool prices are attracting new converts to these breeds, but in the end they are really losing money because under poor conditions poor feed, etc., the size is reduced, the wool clip lowered, the vitality of the sheep naturally delicate is depleted and his losses would be numerous.

Climatic conditions in the province are not favorable to the long opened wooled breeds. The late cold rains and snows of the fall and winter months find a resting place in the valley formed by the parting of the wool along the sheeps back. This causes colds, etc., the system is depleted and they readily fall victims to other diseases which happen along. With good pasture conditions, with plenty of available feed, and under the management of a shepherd or farmer well versed in sheep lore, conversant with the various preventative measures so necessary to maintain the health of the flock a farmer is justified in choosing one of the long wooled breeds. Without these conditions he is not.

The Medium Wool Breeds

The Cheviot and Dorset Horn are not generally known in New Brunswick. They are sheep of medius size cutting a medium weight of fleece which is about midway in length between the short wooled and the long wooled breeds. The outstanding feature about the Cheviot is its ability to withstand severe conditions. Pure bred Cheviot rams have always left an impress in the districts in which they have been used. Sheep men always have a good word for the Cheviot. Each year their numbers are increasing, hardiness, freedom from disease, their activity, and prolificacy are sure pasports to favor with the farmer. The Cheviot ram is an active one, few ewes escape getting in lamb, his virility is astonishing. In the province of Quebec many farmers have found it advantageous to use a Cheviot ram on grade Leicester stock. This cross is epecially recommended by Professor Barton of McDonald College. It might be mentioned here that Professor Barton has been largely instrumental in bringing in some of the finest Cheviot stock to be found in Canada. The Cheviot should be used more and more in this Province especially where the pasturage is inclined to be scant. As a breed the Cheviot is considered very nervous and unless properly tamed, they will develop into jumpers.

The Dorset Horen has its admirers in certain sections where it has gained considerable of foothold, noticeably in Charlotte County. Personal experience with this breed has been limited. They are of medium size, not as active as the Cheviot and from my experience, not as hardy or as healthy. Prolificacy is an outstanding feature of the Dorset, yielding as it does two crops of lambs a year if given an opportunity.

The Short Wooled or Down Breeds

The Down breeds wth the exception of the South down are becoming increasingly popular each year. The Southdown is not a utility breed and has nothing to recommend it to the New Brunswick farmer. The Oxford, the Shropshire and the Hampshire are utility breeds in the truest sense combining as they do both mutton and wool producing qualities. These three breeds have many things in common, black faces, the wool is very similar in length and quality, all are close wooled, hardy, healthy and quiet sheep. The Hampshire and Oxford are rather more upstanding than the Shropshire and appear larger than they really are. The Shropshire ram lamb due to this low setness and extreme compactness is not looked upon with favor by farmers that have not had previous experience with it. However when placed on the scales it will be found to comparefavorably with ram lambs of most of the other breeds.

The wool grower or porspective wool grower must not be guided by the time honored saying "There is no best breed." There is a best breed. In choosing this "best" breed use judgment. . There is a place for the long wooled breeds in the hands of a man well up in the sheep business. They demand good pasture and exceptionally good care and treatment. For average conditions the farmer will not be far astray in selecting one of the Down breeds such as the Shropshire, Oxford or Hampshire.

The Cheviot for rough and hilly country will prove profitable where other breeds would result in a loss.

KEEPING THE SOIL STIRRED ALL SUMMER

There are a number of good reasons why we should keep the soil stirred in the latter part of the summer. The value of a dust mulch will be realized in the more abundant harvest and all work along this line pays when the rains cease.

The corn needs a plentiful supply of moisture at no other time as much as when the ears are forming and filling. At no other time can a good mulch of th esoil over the cultivated field be put to better use. And this is too often the time when the farmers have iald by their crop anad resigned their work to the future and the elements.

The surface, if left unstirred at this time, soon cracks into a mass of hard, irregular clods with every hot drying breeze circulating between them. These crevices widen and deepen and the soil dries out rapidly. We have found these crevices in the cornfield to be two feet deep in dry times. All the roots that cross these fissures underground are dried and broken and the crop yield lowered accordingly.

Frequent shallow cultivation will prevent these crevices from forming by filling each with a fine sift of dust at its start. . These will form as sure as the ground dries and we must arrange to keep it from drying. We have dug through a good mulch even after periods of prolonged dry weather in a healthy field of corn and found the undersoil moist and well able to sustain the crop until maturity.

A light, one-horse harrow or drag answers the purpose well for fitting the surface for retaining moisture. The finely granulated soil is crushed into the new fissures as formed and the crackling is checked where the weekly cultivation is resorted to. Instead of a few large crevices being formed between the hils to break the roots and dry out the soil, a fine system of aeration is set up, through the formatioin of small fissures of shallow depth. We want some air in the soil but not the hot drying blasts that penetrate the unstirred soil.

An old mow or corn planter wheel will answer this purpose as it both pulverizes the soil and drags the crevices full. The wheels are rouding and sli pbetween the rows easily. This also destroys the late summer and fall weeds in their susceptible stage. Especially is this recommended when the corn ground is to be sown to wheat.

KILLING MUSTARD WITH BLUESTONE

The demonstrations given throughout Ontario for the destruction of wild mustard have proved that in the majority of cases, under favorable conditions spraying with copper sulphate almost entirely eradicates the troublesome weed from growing cereal crops.

1. How the Bluestone is applied:—Place an ordinary spray pump to which is attached the 6-row sprayer, on a cart or light wagon; drive along slowly through the field, applying the solution to the mustard plants in the form of a fine spray. When the field is badly infested it is advisable to spray the crop in strips in order that no mustard plants may escape the spary.

2. How the Blue-Stone solution is made:—Put nine (9) pounds of Blue Stone (Copper Sulphate) in a coarse sack or bag and suspend it in a vessel containing three (3) gallons of very hot or boiling water. The Blue-Stone will usually dissolve in 15 or 20 miuutes. Strain the solution into the barrel of the spray pump and fill up with cold water to make 40 or 45 gallons.

3. When to spray the mustard plants:—Spray the mustard on a calm, bright day, just as the plants are coming into bloom. Should a heavy rain come immediately after spraying it will be necessary to spray again.

4. How much is required to spray an acre thoroughly? A barrel of the solution costing about eighty or ninety cents is sufficient for an acre. Successful results are obtained when the spraying is done thoroughly.

5.—Are the crops in which mustard is growing hurt by the spray? Experience sows that the young wheat barley, oats or young clover plants are not injured beyond a slight browning for a few days by the Blue-Stone spray.—Botanical Department O. A. C., Guelph.

The Cotton Seed Meal Supply

—o—

Price will be Fixed by the United States Food Controller---Maritime Farmer will Endeavour to Get Import License for Agricultural Societies

The Maritime Farmer has been advised by one of the largest United States mills engaged in the production of cotton seed meal that the price for the 1918 crop will be fixed in a few days by the United States food controller. They also advise up that they will supply us with our requirements for 1918-19 if they are allowed to export to Canada. The Maritime Farmer is willing to buy for agricultural societies whose members are subscribers for this paper. We saved a lot of money for buyers last year and could have saved thousands of dollars more if the societies had been awake to their opportunities. Before this feed can be imported, it will be necessary to apply to Ottawa for a license. It is there fore imperative that orders be placed at once. When ordering remember that we will not handle any lower grade than 36 per cent. protein and an even higher grade if it can be procurable. The shippers will make draft on your society representative and it will be necessary when ordering goods to have your bank notify us that the draft for the car or cars will be paid promptly on presentation. All goods will be shipped subject to sight draft attached to bill of lading and shipping order. This means it must be paid on presentation and the railway held responsible for any losses. Last year the Maritime Farmer landed 38½ per cent. protein meal for $49.50 per ton. What did you pay for a much lower grade of cotton seed meal in 1917? Get your society busy and send your order in early.

CANADIAN MANUFACTURERS SPEAKING "FRANKLY AND SINCERELY"

On another page of this issue appears an announcement entitled: "Mr. Farmer— we believe you to be fair" sent to us on instructions from the Canadian Manufacturers' Association and the insertion of which is being paid for by that body.

This article is the subject of an address delivered before the Canadian Manufacturers Association in convention assembled at Montreal on June 15th by Mr. S. R. Parsons, the retiring President of the Association, and reflects the carefully thought out views on the important subjects of Tariff and Labour held today by the Canadian Manufacturers Association. The article is worth careful reading, as the viewpoint of the Manuafcturers should be, at least, understood by the farming community.

THE MARITIME FARMER.

And Co-operative Dairyman
Registered Trade Mark

Semi-Monthly Journal devoted to the interests of the farmers of the Maritime Provinces.

Official Organ of The Farmers and Dairymen's Association of New Brunswick; The Nova Scotia Farmer's Association; The Nova Scotia and P. E. I. Fruit Growers' Associations; The New Brunswick Fruit Growers' Association; The Maritime Stock Breeders' Association; The Maritime Bee-Keepers' Association; The New Brunswick Poultry Association, and the Newfoundland Agricultural Board.

Subscription price $1.00 per year. This paper is sent to subscribers unless a definate order for discontinuance is given.

The date after your name on the little green label on front page, is in every case the time to which your subscription is paid.

OUR GUARANTEE.—With each subscriber to the MARITIME FARMER, we positively guarantee, while his subscription lasts, that no advertisement is allowed in our columns unless we believe that any subscriber can safely do business with the advertiser, and we agree to make good any loss which any such subscriber may sustain by trusting any such advertiser who may prove to be a deliberate swindler; but we do not undertake to adjust trifling differences between subscribers and responsible advertisers. To take advantage of this guarantee, written complaint must be made to the publisher within one week from the date of any unsatisfactory transaction, with proof of the swindle and loss, and within one month from the date when the advertisement appeared, and the subscriber must prove that in writing to the advertiser he said:—"I saw" your adv. in the MARITIME FARMER.

VALUE OF LOCAL BREED ORGANIZATIONS

Local breed organizations are essential to the progress of pedigree live stock production. In no other way can the cause of more and better live stock on the farms be given such an effective stimulus as results from the cooperative work of breeders in a particular section, whether it be in behalf of one breed or of all. In union there is strength. In concerted effort the thing to be accomplished is made easy, whereas individual effort may fail of its purpose, entirely. The cooperative plan has worked out so successfully wherever tried that there is no valid argument to be made against it.

The problem with the beginner in the pedigree business is that of finding a market for the surplus products of his herd or stud. When he adds to his farm investment pedigree breeding stock, he is in a measure operating a factory and the products of that factory must be distributed. At first the stock to be offered may be one or two bulls or stallions, too small a number to attract buyers with an individual advertisement. If such a small number must be shipped quite a distance to some sale center the expense is out of proportion to the selling price.

Suppose there are quite a number of such small holders in that county or district, each one of whom faces the same problems. Working individually and perhaps at cross purposes, little is accomplished; returns are slow and sooner or later discouraging features are to be faced. Reference of course, is made to the beginner who embarks on a limited scale and whose most trying time is the first few years of his venture. But where there is a live county organization the story is different. If there is a sufficient number of breeders of any one breed from whose herds may be drawn enough stock for a sale, that will justify the essential publicity, buyers are attracted from near and far and the products of the small breeders, the various little live stock producing factories in the county, are absorbed at profitable prices. The members have added a most profitable adjunct to their farming operations. Co-operation has taken the place of the go-it-alone plan and cooperation in such instances removes many obstacles which confront and obstruct the path of success of the beginner and shows the road to success.

Such organizations are most practical and successful and are doing effective work in many sections of the country at this time. A case in point is revealed in a study of the workings of the Fort Wayne District Shorthorn Breeders' Association at Huntertown, Ind. A few years ago a few struggling Shorthorn breeders in that section of northern Indiana had made average progress, but no more. Nothing out of the ordinary had been done to attract buyers. A few years ago one of the breed's best "boosters," Will Johnson, got busy on an organization and one of the strongest, most active and most effective Shorthorn breed organizations of the country was effected. Semi-annual sales have been held for a number of years and the surplus of the herds of the members has gone to other sections of Indiana and to other states at good prices. The problem of what to do with the products of the herds is most efficiently solved. There is another result growing out of the success of this organization and that is that the members have strengthened their herds by the purchase of a higher grade of females and bulls of more merit have been secured for service. In a few instances a number of neighboring breeders have gone together and purchased a bull for joint use and secured a better one than would have been taken there had any one individual had to go it alone in the purchase. The draft horse breeders in the same section have an active working organization and are also getting results.

What has been done in that section may be done in any other section. We would urge that similar organizations be effected everywhere for these mean prosperity to the small breeder and his prosperity insures that of the larger one. It does more. It means better productions. It means better conditioning, and these mean better values to the owners. There is nothing that so stimulates the young breeder towards the production of better live stock as the comparisons and the values placed on the different lots in a consignment sale, as the member who is not ambitious to present stock which will command the bids of the discriminating buyer is not making the most of his opportunities. We would advise pedigree breeders to organize local associations and attract the attention of buyers to their section as the place to go for good breeding stock. Prosperity to the individual and to the community will be the result.

TEAM WORK FOSTERS EFFICIENCY

Fall into line. It is not so much the old individual effort that counts to-day as the new concerted one—the drive made up of both veterans and recruits. One of the lessons we as Canadian men needed to learn was to do team work. And we are learning it. We have passed that old Slough of Despond which threatened to end Pilgrim's immortal progress—distrust of ourselves and others—and are up and away towards heights of practical endeavor, aye, and achievement undreamed of before we united our forces.

Now comes into working order for the first time the utility of team work. No more of the conceit which laughs our amateur efforts to scorn, but a whole-souled sympathetic merging of seasoned veteran and raw recruit for the accomplishment of a duty lying near the heart of every one of us. The more team work we do the closer we will come to that unity which spells strength and confidence and faith in each other. So no more balking among you veterans; the beginners need your co-operation, not your criticism.

You know what the Berlin war report said of our men after a battle: "There was no keeping them (Canadians) back, they came on rushing, shoulder to shoulder." Shall their example be wasted upon us?

Team work is what tells. "And the Old man proffered a twig, and bade the Young man break it. When he had done this, the Old Man made a bundle of similar twigs and bade the Young man break them also. This the Young man could not do, and the Old man exhorted him to observe how in union lieth strength." No more misunderstandings, no more fueds, but shoulder to shoulder, a long pull, a strong pull, and a pull all together.

SAVING THE OUNCES

You have perhaps seen a grasshopper eating in an immense meadow and paid no attention. But if you have seen thousands, hundreds of thousands of grasshoppers eating their way steadily through a fruitful field, devastating the crops as irretrievably as the elements themselves, perhaps you have been impressed.

You are the integral unit of that vast civilian army which can similarly destroy the food stores essential for our armies and those of our Allies.

Save two ounces of butter a week? What are two ounces? Eaten or wasted they'll never be noticed. But figure it out for your own home. You have four people in your family? Well, two ounces would be multiplied by four and you'd have half a pound saved every week. You can think of that more easily. And from that it's no trouble at all to see that in a year's time you have released to the army twenty-six pounds of butter—full rations of this food for a soldier for six months. And "fats make fuel for fighters."

A pound of wheat flour seems trifling. Why, it's less than a large loaf of bread! And a loaf of bread for each member of a family of four doesn't loom very large in the week's budget of menus. For one person it is less than a slice a meal. It can matter so much that this saving on the part of your family for one year, would give a soldier fighting at the front a loaf of bread every day for half a year.

It is the same with other things, meat and sugar, at the individual rate of seven ounces a week, accumulates ninety-one pounds as the family's annual contribution to a soldier in each of these important staples. And it would be a generous supply. And it would only mean giving up a few lumps of sugar every day.

* * *

Are you sending a son o ra daughter to college this fall? The maintenance of our national intellectual balance is of vital importance in times like these.

* * *

Remember that the wind, not sun, cures the hay. The one place where hot air pays on the farm.

* * *

Remember that you do not raise hay or grass for the seed, but for the leaf and stalk. They are best before the seed fully forms.

A stomachful of wholesome food
For every Allied fighter,
Will mean a stomachful of war
For Bill—the Divine righter.

KEEPING THE FLOCK IN HEALTH

(Continued from page 677)

about three days. two or three treatments usually being sufficient to practically rid the animals of infection. After such treatment it is highly important to keep the animals in a good thrifty condition so that they will be able to keep free from infection.

During the winter months, the disease known as gid causes the flock owner more or less trouble in most section of this country. This disease is caused by the cystic form of a tape worm common to dogs, foxes and wolves. The eggs are passed out with the feces of those animals and when taken up with the drinking water ot the sheep hatch out into the larva form which finally finds its way to the brain or spinal cord. Here it develops causing pressure on the brain or spinal cord of the sheep. The symptoms produced are clearly those of brain trouble, causing the animal to travel in a circle or stand with its head pushed in a corner or against a wall. Little or nothing is practical in the way of treatment. However, the disease can be prevented by providing the flock with water uncontaminated with he feces of dogs, foxes or wolves which harbor the adult form of the tape worm. Of course, it goes without soying those animals should never be allowed to devour the carcass of sheep having died of the disease—a method by which the disease has been sprea don the wetsern ranges.

A parasite causing the sheepman considerable annoyance is the larval form of the sheep gad fly. The adult fly is somewhat larger than the ordinary house fly. During the summer months the female deposits her eggs around the nostrils of the sheep; in a few days they hatch out into the upper part of the nasal cavity. Here they remain during the winter in the form of a grub, about three-fourths of an inch in length, causing the affected animal considerable irritation manifested by a discharge from the nostrils. The condition rarely produces death, the loss being that if lessened gains and loss of condition. Probably the most practical way to prevent infection is to smear pine tar about the noses of the flock during the summer months, which will generally keep the adult fly away from the sheep. This can be done in a practical way by boring two concentric holes in a log, the smaller the deeper. Salt is placed in the bottom of the smaller hole, while pine tar is smeared around the larger. When the animal comes to get salt, it will then automatically smear its nose with the tar. In cases of valuable animals, it is sometimes advisable to have the grubs surgically removed.

The liver fluke is a parasite that occasions considerable loss in the southern half of the United States. The worm is lance shaped, about three eighths of an inch in length. The adult form lives in the liveh where it causes diseased yellowish nodules, each of which contains one of the flat ovoid worms. As the fluke requires the snail as an intermediate host, and as the larvae are taken in with the drinking water, plainly the mode of prevention is t oprovide pure water and well drained pastures. Once an animal is infected but litttle can be done in way of treatment aside from giving it extra care and if possible getting it read yfor market. Lambs are most often affected.

This by no means exhausts the list of internal parasites affecting sheep yet it includes most of the important ones found in this section of the country. In general, it may be said that pure water, pasture rotation, thrifty animals and medicinal treatment will in a large measure control parasitic diseases. Too much emphasis cannot be laid on pure water. The flock should never be allowed to drink water out of pools or water that drains from a sheep pasture. The ideal pasture is high, dry and well drained. Another important factor in the prevention of parasites is to eliminate all unthrifty animals from the breeding stock. The vigorous growing lamb is less likely to become a host to the various parasites than the unthrifty one.

External Parasites

So far as the external parasites are concerned, their control is easy. If the flock is dipped twice in the spring and twice in the fall at intervals of about a week, no trouble will be experienced from ticks, lice or scabies. The spring dipping should be immediately bright, still day should be selected for the job, both spring and fall, or colds and pneumonia are liable to result. The dip should be kept reasonably warm (about 110 degrees F.) if greatest efficiency is desired.

Relatively few drugs are used internally in the treatment of sheep diseases. This is due to the tendency of the animal to give up as soon as it gets sick. Epsom or Glaubers saltts given in three to five ounce doses will generally relieve impaction of the first stomach or constipation, both of which are usually brought on by diatetic error already discussed. Diarrhoea can usually be controlled by bismuth and salol, equau parts, given in one-half teaspoonful doses every three or four hours.

A few drops of spirits of camphor or a few inhalations of aromatic spirits of ammonia will often revive a lamb apparently born dead. Artificial respiration should always be resorted to in such lambs. . During the lambing season the ewes should be watched closely for unborn dead lambs. improper cleaning following lambing or difficult partruition due to faulty presentation of the lamb. If the lamb is to be saved, the latter condition must be relieved promptly. If the ewe continues to discharge, the uterus (womb) should be flushed out carefully with a 2% lugols solution in water heated to about 105 degrees, or therapogen 1% solution, may be substituted for the lugulos solution. The first two mentioned drugs are to be preferred, however.

What is known as mastitis or "caked udder" or "'blue bag" is quite common in ewes. It is a difficult condition to treat, yet it responds fairly well if taken in hand early to tincture of iodine one part, and spirits of camphor two parts, painted on the udder twice a day. The udder should be milked out often and carefully. The male lambs should be castrated when they are about two or three weeks old. For this operation it is well to choose a warm sunshiny day. Avoid causing the lambs to be castrated undue excitement while catching anad do the operation as quickly as possible, removing as much of the cord and membranes surrounding the testicle as possible. Rapid work to lessen the pain and shock to the lamb is essential to successful operating. During fly time the scrotum should be smeared with pine tar after the operation to keep flies away.

Another trouble that causes the flock owner considerable annoyance and often serious loss is bloating. This is most likely to occur when the flock is on clover pasture following a rain or heavy dew on hot sultry days, although it may occur at any time of the year or in any kindw of weather when the flock is on grass. Treatment consists of drenching the animal with one-half of one per cent. solution of creolin, or coal tar dip. The solution is more effective if warm. Fresh cow's milk is also used successfully when there is time to obtain it. If nothing else is at hand, use plain water. The mechanical effect of swallowing will often start the animal erupting the gas. It is generally necessary to act quickly and too much time cannot be taken to find a remedy if successful results are to be obtained.

(I. D. Wilson, D. V. M. Pennsylvania State College, in Amercian Sheep Breeder.

SPRAYING TO PROTECT THE POTATO CROP

You insure your barns against fire. Why not isure your crop against disease? The insurance company protects you against loss by fire. Spraying will protect your potato crop against loss from disease and insects.

In these war times spraying is more necessary than ever. Labor is short. Use it where it brings the greatest returns. Spraying doubles the bushels produced per day of human labor.

Fertilizer is hard to get. Spraying will make it more effective—make the supply do more in terms of food produced.

The entire profits of the year may be wiped out by blight within a couple of days unless you spray to protect your investment. You can't afford to take such a chance this year.

The old Colorado shellback comes out of the ground almost as soon as the plants. She lays her eggs, which soon hatch. The slugs have enormous appetites and proceed to use them at once.

Be ready for the slug. It takes a deadly poison to kill him. Give him some poison in one form or another with his first meal. It takes less poison to kill a newly hatched slug than to kill an old shellback, and the poison acts more quickly. After a bite or two of poison the little slug becomes a dead bug, and you see neither the bug nor any damage to your crop. You will feel better satisfied if you kill the bugs and flea beetles before they eat the leaves than afterward. Why grow potato bugs?

While you are spraying for the Colorado beetle you may as well include a spray for the flea beetle and for blight. They are all due to arrive at about the same time. You can save time and labor by applying both sprays together, and it works even more effectively.

Flea beetles by the millions arrive as soon as the weather warms up and the potatoes get well started.

They riddle the leaves, "shoot them full of holes," and so weaken and injure the plants that they fall easy victims to early blight—a disease that comes along with the beetles.

It is hard to poison the flea beetles—they don't stay long enough in one place. Many growers have found it almost impossible to get rid of them with Paris green or arsenate of lead alone, but by using a copper fungicide spray for blight, either factory made or home-made Bordeaux with arsenate of lead, you can get rid of the flea beetles, and at the same time this spray will prevent the next trouble, the so-called early blight. Even if the potato bug and flea beetles fail to appear, spray just the same. Remember that spraying is prevention and not a cure. When the blight appears, the game is lost.

Early blight first appears as small brown spots on the leaves. These spots run together, the entire leaf turns yellow, withers up and dies. When the growth of the plant is stopped, the yield is cut from 10 to 25 per cent.; the potatoes are small, unripe and of poor quality.

Often the cause of the loss is not recognized, because this disease never causes rot. The potato grower thinks that the crop simply ripened prematurely.

In spraying against the flea beetle the first step is taken toward preventing early blight. The spray mixture on the leaves kills the spores whenever they strike. But the spray must be there first.

The next step is to repeat the spray whenever the vines outgrow their protective covering, or the spray is washed off by beating rains.

With the coming of cool nights, frequent showers and heavy dews, conditions become ideal for the late blight —the blight that causes soft field rot of the potato.

The infection is caused by spores—small seed-like bodies—which are carried through the air by millions, and which may attach to any part of the growing plant.

As with the early blight, whenever the spores of the disease come in contact with the spray covered leaf, they are killed. **But once let the disease get started and no amount of spraying will effect a cure.**

A mist spray, not a sprinkle, is best, and power enough must be had to drive the swirling mist over all the plant, on top, at the sides, underneath. Spraying the under side of the foilage is most important. A spore lodging on the under side of the leaf is more likely to live and do harm than a spore falling on the top of the leaf, because under the leaf there is more moisture and less sunlight to give a drying effect.

One nozzle per row is enough to start with; but for the later spraying two or more nozzles are needed, and with the powe rbehind them to make an effective spray.

As long as the vines remain green, they should be kept covered with spray. The gain from late sprayings much overbalances any damage that may be caused by the machine in passing through the tangled rows.

You can't insure your barn after the fire starts. Neither can you protect your potato crop after the blight appears. You must be there with a spray before the spores arrive, and stay there with a spray as long as the danger lasts.

IT IS TIME TO SPRAY POTATOES

The U. S. Government report is out which shows that the state of Maine has only 112.000 acres in potatotes this year, a falling off of 38.000 acres from 917. The decrease in the New Brunswick potato acreage is about the same There is not a state in all New England that has more potatoes planted than last year.

If there is a full bumper crop of potatoes this year there will probably be enough to go around; if we have as much blight as last year it is hard to say how short potatoes will be or how high the price will be, but it seems probable that with average blight conditions, the crop will be short and the price high.

The test on the Annapolis Royal School plot last year showed that the unsprayed plot gave 75 bushels per acre while the sprayed plot gave at the rate of 221 bushels per acre. At St. Anne's College at Church Point, the plot sprayed under the direction of Father LeChantoux gave 300 bushels per acre while the unsprayed portion of the field yielded at the rate of 150 bushels per acre. Tests at various stations over a period of years show an average increase of from 90 to '00 bushels per acre due to spraying.

Bordeaux made according to the 4-4-40 formula to which any of the common poisons may be added with safety is the standard potato spray. Bordeaux may be applied in any way that will wet every portion of the plant. The best method of application is of course the traction sprayer or a power sprayer and a spray gun. A hand or barrel sprayer or even a knapsack sprayer will do good work if one takes enough time or if one has no other means of applying the spray. a common garden watering can or a bucket and a whisk broom may be used. The idea is to wet every portion of the plant by one means or another. Apply the first spray if possible before July 20 and repeat every two weeks until frost.

In one field last season the sprayed plants remained green for 40 days longer than the unsprayed The increased yield in that case was slightly over 200 bushels per acre. Every day a field is kept green it stores or grows about 5 bushels of potato tubers per acre. Three days growth will pay for all of the material and labor for spraying five times.

No one can afford not to spray their potatoes this year.—By G. E. Sanders, Dominion Entomological Laboratory. Annapolis Royal, N. S.

HORTICULTURE

WILD BIRDS THAT ARE FARMER'S BEST FRIEND IN FIELDS AND ORCHARDS

Birds are gardeners' best friends. This has been said many times before, in many ways, by many writers and observers. But it is one of the things that can bear repetition, and if anything new and compelling can be said, the repetition will be well worthy of attention. Besides, very, very few understand the extent of the birds' help in raising each year's crops.

When the writer was a boy on a farm, birds were loved in a way and their songs were appreciated; but in their relation to the crops they were regarded as enemies rather than helpers. The red-winged black-bird was thought of as the robber of planted corn, not as the devourer of cutworms; robins, thrushes, purple grackles, and many others, were regarded as cherry thieves, not as the slayers of worms and insects innumerable that mar fruit and cause imperfect vegetables; the kingbird was looked upon with favor because he killed the flies that bit us—which was a small matter, not because he killed the flies that sting fruit, lay eggs in it, and make it "wormy"—which is a very large matter.

One who begrudges birds the little fruit which they may eat in the fruit season is apt to forget that the fruit season is very short, while these helpers are working for him the year round. In the winter the woodpeckers, nuthatches, and brown creepers, are literally climbing up his trees—gathering insect larvae and eggs from trunk and limbs, bark creases and knot holes. In the spring, when leaf and flower buds are bursting, when all foliage is tender, and insect larvae begin to devour, warblers, greenlets, and kinglets come from the South by hundreds to search every delicate crevice and cranny of leaf, bud, and blossom; and were it not for these mighty pigmy hunters, our trees, fruit, and vegetables would literally be at the mercy of insects. Then, all summer long there remain with us bluebirds, wrens, robins, grosbeaks, kingbirds, flickers, orioles, thrushes, catbirds, all of which, while incidentally building nests and rearing young, spend most of their time protecting our trees, fruit and vegetables.

The greater portion of the food of these birds consists of noxious insects; and when a bird is not nesting or singing or sleeping it is usually searching for food.

It should be noted, also, that most birds feed their young entirely upon insects; and the open mouth of the hungry bird is proverbial. Most of our common birds raise two broods a year. Think of the number of insects necessary to feed from twelve to sixteen young wrens, or eight or ten young robins! Young birds grow so rapidly that the amount of food they eat is simply astounding. I have held my watch on a mother oriole for hours while she fed her young, and she would come with food every three or four minutes, very seldom failing to come within five. When young birds fill the nest this process goes on, with only short intervals, from early morning until evening.

The important question for every one, however, is, how shall the birds be induced to gather their insect food in his particular garden?

A number of suggestions will here be made, but the first and the most important is, give the birds water. Last spring I took a wooden chopping bowl, placed in the bottom of it a chunk of sod, from the roots of which I had washed most of the dirt, filled it with water, and set it on a post which I had driven down in the middle of my back lawn. My flower and vegetable garden were only a few paces away, and both lawn and garden were surrounded with trees.

There was scarcely a day during the summer when birds did not come to drink and bathe. The post was made sufficiently high to protect the birds while bathing, from the cats; and they liked the sod in the water, as it made a good safe bed for them to bathe upon, and the long spears of grass sticking above the water gave them confidence.

The reflection from the surface of the water, like that from a mirror, could be seen for a long distance, and this bird bath became the centre of bird life for the whole neighborhood. Robins came hopping upon the lawn to it; kingbirds descended from the clothes-line; the flicker shot down from his nest in a nearby trunk; orioles came from a neighboring orchard; grosbeaks crossed the road from their nest in an adjoining yard; catbirds ventured from a clump of shrubbery a block away; blue jays darted in, now from one direction and now from another, without revealing the locality of their home; bluebirds dropped down occasionally as though out of a clear sky; and all the while the wren, whose nest was in a box in a corner of the yard, seemed to consider this his private bath.

These birds in coming and going visited every part of the yard—trees, garden, bushes, fences.

It would have been best for the garden had the bath been placed on a stake about two feet high right in the middle of it. But I placed it in the lawn for the pleasure of watching the birds. Robins would almost invariably hop across the lawn to the bath, picking up half a dozen worms and beetles as they came; the kingbird would sit on a wire clothes-line and dart out every few minutes to capture an insect; the orioles would stop, either coming or going, in two plum trees to feast on caterpillars; the blue jays would often perch on near-by posts, or even on the rim of the bowl, to watch for the movement of insects in the grass, and every few moments they would dart down to seize them; the flickers found a table spread with their favorite dainties in an ant-hill a few rods distant; the familiar clicking notes of the grosbeak were heard for some time as they fed in the box-elders, before descending to drink or bathe.

Birds are always in search of food. The necessary thing in securing their services for one's garden is simply to place in or near the garden what will attract them to it. They will do the work as they come and go. And it is this coming and going process that is important, for it brings many birds to one's help.

Some, to attract birds, put up nests for them—for wrens, martins, and bluebirds. It is true that where any birds are heard and seen, other birds are apt to be attracted, as though to see what is going on. An extreme case of this attraction is seen when a snake, cat, squirrel, or jay assails some nest. All the birds of the neighborhood are gathered at the cry of the victims. But it is also true that among birds there is a general understanding that wherever a bird builds its nest, a certain area around that nest belongs to the owner. I have seen the kingbird, whose nest was in a solitary tree, attack every bird that approached. I have seen robins unceremoniously hustled out of trees where blue jays had their nests; and not long afterwards I have seen blue jays hustled out of trees where robins had their nest. To be sure, the blue jay is an egg-eater, and that fact would account for the attack upon him; but the robin never molests a nest, and the attack upon him is due to the fact that the region for some distance around a bird's nest belongs to the birds that built it, and every ther bird is regarded as an intruder.

I once placed in my back yard, close beside a bird bath, a home for a pair of bluebirds. The result was that the bluebirds thought they owned the yard. Many a fracas did I see between them and other bluebirds that happened in. To the jay that came to the bath to drink, the male bluebird gave no peace, but kept him busy ducking his head to save it from his strokes. And a robin that, after bathing, rose in lumbering flight to the top of a high post, the bluebird plunged into and actually knocked to the ground.

If the bath is put out early in the season the birds will discover it and build their nests in various places in the neighborhood convenient to its use.

In connection with the bath it is of great importance to erect two or three high posts, and between two of them at least to string a tight wire or rope. Simply by focusing my camera upon the top of a high post placed in the middle of my back yard, I have secured the photographs of many of the birds that entered the yard during the season.

These posts serve as perches from which the birds watch for insects moving on the ground, in the grass, or among the leaves of vegetables. The kingbear will one moment dart into the air to take a fly, and the next, descend to the ground to seize a beetle. The blue jay may be seen cocking his head now on one side, now on the other, and every few moments dropping to the lawn to take an insect. Who

Be Sure of Your Weight

Be certain the goods you buy and sell are correct weight. Accurate weight is assured by

Fairbanks Union Scales

They are the most convenient size scales for general light weighing anywhere. They replace the old time spring balance scales condemned by the Canadian Government. Complete with tin scoop, 10½" x 13½" platform, single brass beam and extra weights. The scoop capacity of Fairbanks Union Scales is 30 pounds by half ounces—the platform, 240 pounds by quarter pounds.

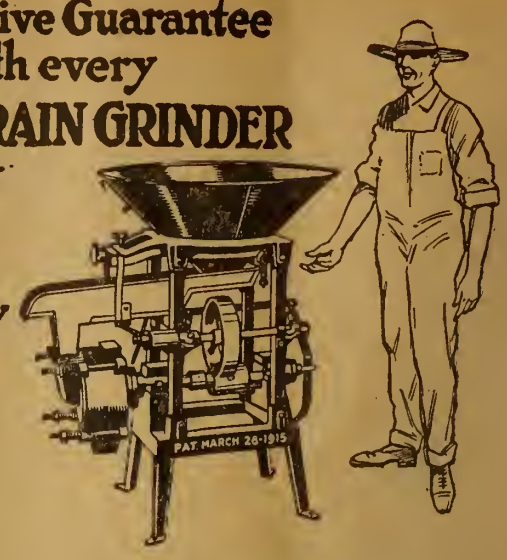
A Positive Guarantee goes with every MRE GRAIN GRINDER of money back if not completely satisfied.



If the M-Re Grain Grinder does not give you better chop in less time and for less money you have only to return it and get your money back.

Could we possibly make a fairer or more generous offer? Over 1500 M-re Grain Grinders have already been sold with that guarantee and not a single one has ever been returned. Every one who has ever tried it has been enthusiastic about it.

The M-re is a Revolution

The M-re grinds with emery wheels instead of steel plates or discs. Steel plates slice the grain, while the M-re thoroughly grinds it to a fine powder. Its chop is as superior to that of the steel plate grinder as the electric light is to the oil lamp. There is simply no comparison. Then the M-re is the only grinder that will completely destroy wild weeds. The emery wheels can be dressed in a few minutes and be as good as new and they last three or four times as long as the steel plates. Have one of these machines sent to you, put it to as thorough—as severe a test as you wish. If you are not more than pleased and satisfied with the results, simply say so and we will refund every penny of your money.

has not seen a red-headed woodpecker perched on a post by the roadside, and wondered what he was doing there? I one day held my watch on one for five minutes, and during that time he descended to the ground for insects five times, and took one in the air as do the flycatchers. He was simply using the perch for observation. Such posts in our gardens give the birds twice the chance to see injurious insects which they otherwise would have.

If one thus attracts birds to his garden he will find that they soon learn to be on hand when any plowing, spading, hoeing, raking or weeding is going on; for it is when the soil is disturbed that worms and insects are brought to the surface and in approaching near to the worker to secure them, the birds, especially robins, become almost as tame and bold as chickens.

Black-billed cuckoos, kingbirds, orioles, are all very active in destroying bettles, grasshoppers, spiders, weevils, caterpillars, ants, and click-beetles, the larvae of the latter being among the most destructive insects known. The grosbeak is the particular enemy of the potato beetle, while the robin, the house wren, the bluebird and catbird are all shown to subsist mostly on animal matter, the greater portion of which consists of insects.

F. H. SWEET.

LIVE STOCK AND THE ORCHARD

There has been in Western agricultural practice a strong tendency for several years toward specialization. In so far as this has meant for more intensive methods and for greater intelligence and skill devoted to the production of special crops or special farm products, the movement has been worthy of high commendation. Weaknesses have been found in the system, however, and the trend of today is away from extreme specialization and toward diversification in the handling of the Western agricultural farm holdings.

NOW IS THE TIME TO PLANT

WINTER CABBAGE PLANTS

HEROLD'S FARM
FRUITLAND, ONTARIO
Dept. "L" Niagara District

A fundamental difficulty for the man of limited means in any plan of high specialization is that he does not, and probably cannot afford to prepare himself for a season of loss. It is not always entirely well with a specialty. Whether it is with the cereals or the forage crops of the field or the crops of the orchard, there comes a season when conditions are unfavorable and the income is small. With the fruit grower, furthermore, there may be the problem of the orchard not yet in bearing and diversification offers at least part solution for the problem of maintaining the family until the orchard is of bearing age. Diversification, therefore, does not run counter to the best interests of the fruit grower, but on the other hand, assists in increasing his income and in staving over certain periods when the orchard is young or when, for some reason, it does not yield in abundance. A modern slogan that is now quite popular in the agricultural field is the warning not to put all the eggs in one basket.

There are four direct reasons why the orchardist should be able to find a use for live stock in connection with his main business, which is that of fruit production. In the first place the live stock furnishes an additional source of income and often contributes directly to the support of the family by furnishing animal products for home consumption. Second, live stock may be made to furnish a market for many of the crops grown by the orchardist between the rows of trees. Some of the crops, such as legumes, roots, grains of various kinds, can, as a rule, be most profitably marketed through live stock. Third, the orchardist needs live stock for the purpose of maintaining soil fertility. We find that more and more fruit men are giving consideration to the question of fertilization and we all recognize that one of the cheapest and most efficient means of maintaining the soil in the best possible physical condition for maximum production is through the use of farm manures secured through live-stock keeping. There is a fourth reason why the orchardist should at this particular time think seriously of live-stock production. This is because the leaders of the American overnment today are calling for more animals and more animal products. The larger share by far of the needs of the nation in this direction will, of course, be taken care of on the ranges and on the farms. The fruit grower, however, can aid materially in this direction, and if a few head of live stock were kept on the average fruit farm of the West the sum total would be of real assistance in meeting the present-day needs of America.

Granted that live-stock keeping is feasible, we may immediately consider the kinds of live stock that are best adapted to the fruit farm. A few horses will always be kept, but many orchardists question the advisability of trying to breed horses in connection with an orchard plant. Beef cattle are produced most successfully and profitably where there is ample room and cheap grass. In a similar way sheep have, in past years, been regarded as better adapted to cheaper lands that are devoted largely to grazing purposes. In the past to or three years, however, hundreds of small flocks of sheep have been bought by the farmer and it will only be a short time, if the present tendency prevails, when sheep on the Western farms will be as common as they have for years been on the farms of Ohio and Indiana. There is a possibility of using a small band of sheep in connection with the orchard. For the average man engaged in fruit growing, however, the dairy cow and the brood sow lend themselves better to his needs. These two classes of animals fit well together on the farm and make a splendid combination for use in connection with the orchard.

Those who are keeping in touch with dairy conditions of today feel that the time is not far distant when dairymen are to be paid well for their work in producing milk and butter fat. Prices

Eureka Potato Digger

Gets the Potatoes and pays for itself in one season. Saves extra help

Potatoes frozen in ground last Fall could have been saved by the Eureka. Works in ground and conditions where other diggers cannot.

The Eureka elevator and duplex shaker provide more separation than other diggers. Large wheels and main gears supply ample power. Special construction avoids frequent breakage and lost time. Growers report digging 150 or more acres without repairs. High clearance over shovel prevents weeds and vines bunching. Has vine-turner attachment.

Specially adapted for use with tractors and for engine attachment.

6-ft. and 7-ft. sizes; several styles.
Prompt shipments from distributing points.

have not been adequate and the dairyman has been losing money for many months. The result has been the selling of a large number of dairy cattle and we will unquestionably soon be face to face with a condition in regard to milk and butter-fat production that will mean one of two things—the dairyman will be well paid or the consumer will do without dairy products. I am familiar with one of the well-known irrigated districts of the West where many of the farmers have made a specialty of dairying. Two of the very best herds of that tract that have been tested and have a wide reputation for high production are now offered for sale. When the best of dairymen are thinking of quitting the business it is well for us to think seriously of the future. It is my opinion, confirmed by many experienced men with whom I have talked, that now is a mighty good time to get into the dairy business. Good cattle are being sold in many sections at quite reasonable prices and, as before indicated, there can be no other outcome than such prices for dairy products of all kinds as will enable the dairyman to meet all costs of keeping the herd and have a reasonable profit for his efforts.

In the orchard may be produced corn, peas and oats, and other crops for silage. The production of legume hays such as clover fit in well with the fertilization of the orchard and give the orchard dairymen the very best roughages for milk production. If the silo is not advisable, root crops can be grown between the tree rows to wonderful advantage. Grains may be purchased or may be grown in connection with the orchard. The combination of legume hay for roughage, of either silage or root crop for succulence, and of our Western-grown grains for concentrates, gives exactly the right kind of ration for heavy milk and butter-fat production. The grains that are needed are barley and oats, in addition to bran, which is now one of the relatively cheapest feeds that can be bought in the market.

The dairy cow, therefore, fits in with the orchard plan for between-the-row crops and not only furnishes the family with highly-nutritious foodstuffs, but in addition gives the fruit grower a week by week or month by month cash income to supplement the income from fruit production.

Swine fit in well with dairy cattle because one of the best of all feeds for growing pigs is the skimmed milk, which on many farms is a by-product of the dairy business. Fundamentals in successful swine production are pasture for the brood sow and pigs; by-products such as from the dairy for supplementing other rations and for keeping down cost of production, and concentrates for finishing swine for market. All of these feeds, to a limited extent at least, can be produced in connection with the fruit farm. The pasture could be legume pasture, either alfalfa or clover. In addition special between-the-row crops such as peas and oats, rape, kale and other crops of a similar nature can be seeded for hog pasture. Skimmed milk, unsalable fruit and wastes from the household may be used in connection with swine feeding. In addition there will be needed concentrates for fleshing swine for market. At present prices of feedstucs, shorts and barley are probably the most economical feed to use in swine feeding. A nitrogenous supplement should be fed in addition and skimmed milk, or clover hay are feeds valuable in this connection.

There are a large number of questions of breeding, feeding and management that should be considered in connection with dairy cattle and swine for the orchard. Time, however, does not permit extensive treatment of these problems unless there is some particular point that needs amplification. It is not only true that dairy cattle and swine are best fitted of the farm animals for use in connection with the orchard, but in addition it is peculiarly appropriate that these animals be bred at this particular time, since of all the animals of the farm the dairy cow is most efficient in that she provides more human food from one hundred pounds of feed, through her milk, than can be obtained through the means of any other animal product. Swine rank second in efficiency to the dairy cow.

There is one other branch of the live-stock industry that should be mentioned at this time, one of the great

DAIRYING.

MILKING SHORTHORNS AND MILK RECORDS

The importance of keeping milk records for Milking Shorthorns cannot be overestimated. It would be claiming too much to say that it would not be possible to produce high-class milkers in the absence of such records, but it is not possible in their absence to tell even approximately how much milk an animal will give in a year. A man may have followed the dairy business for many years; two of his best producing cows may stand side by side under his own immediate handling; yet he may be in error as to which is the higher producer, though he may have milked them through several lactation periods.

Keeping the records of milk production is of great importance in Milking Shorthorns, for a reason that applies to all the breeds and types of milk and meat producing cattle. It is this: in the absence of such records the man who invests in their class of cattle has no sure guaranty that the animals which he buys are really the true Milking Shorthorns. He must rely upon the word of the seller. The latter may be honest in his representations, but if he does not milk his cows he ought to know that they are not Milking Shorthorn. If he does milk them but keeps no records he may be deceived himself as to the relative status of production in his cows.

Milk records when kept should be properly accredited by some outside authority. Where this is not done, a designing man may make his own records. It is to be hoped that this is not frequently done, but the temptation to do this is always present. Many have an aversion to keeping records, based on the erroneous view that it will call for much time. When properly equipped for the work it should not take more than 15 minutes daily to do the marking in the stables. The equipment consists of properly prepared milk sheets and scales to weigh each cow's milk as it is taken. The milk sheet for the time being is tacked up in the stable. The plan most commonly adopted in previous years to check the records was through some official of the experiment station in each state, but this work is now being turned over to the person in charge of a cow-testing association where one exists in the locality. Some expense is involved, but it is small, compared with the benefit.

These cow-testing associations will result in great good to the milk industry. But no class of cattle will be helped more by their presence in a neighborhood than the Milking Shorthorn. They have shown conclusively that average production of the Milking Shorthorn stands up well even when compared with the dairy breeds. The breeders of this class of cattle will do well, therefore, to patronize such an association when the opportunity offers. The milk record sheets will be sent without charge to all members of the American Milking Shorthorn Breekers' Association when applied for.

A practice is becoming all too common at the present time among breeders of this class of cattle that may tend to discourage the keeping of milk records. Quite a number of breeders of Shorthorns are securing Milking Shorthorn males to use upon their females. They are finding that when they con say that their bull calves are the progeny of a bona-fide Milking Shorthorn bull, the result is a much readier sale and higher prices. This at least is true in many communities. The fact that such bulls are coming to be used more than formerly will certainly tend to improve the milking qualities of the animals where they are used, but it should be remembered that this plan will never in itself make genuine Milking Shorthorns. It is impossible to make a Milking Shorthorn sire in one generation, that is, as the outcome of one instance of mating, the dam being a beef Shorthorn and the progeny of such mating being raised on the dam. It would not be possible to produce a Milking Shorthorn from several generations or indeed any number of generations of such breeding in the absence of handmilking. It would also result in reducing to some extent the beef-producing qualities in such a herd.

This practice, however, it is to be feared will be very successful in distributing males called Milking, because they are the progeny of such a sire, when they are not the real thing. The men who practice this may raise all such males on the dams, hence when under one year old they will carry more flesh than the males in real Milking Shorthorn herds in which the young males are hand-raised. We all know the magic influence which much flesh has on the average purchaser of a young bull.

The unfortunate feature of the method of breeding is that it wrongs the man who buys. The young bull thus chosen is taken into a herd, it may be of fair, or even good milking qualities, with the result that in all probability the milking standard will be lowered. The owner of the herd is not sufficiently informed as to what a Milking Shorthorn is. He pays a high price for not possessing this knowledge. It also puts the breeder of real Milking Shorthorn males at a disadvantage when making sales. Such a trade is legitimately his, but much of it he does not get.

May it be remembered by all who are seeking Milking Shorthorns, males or females, that they should be the offspring of several generations of good milk producers. This at least should be imperative in the case of the sires, and it should apply to the dams in the near ancestry of the sire, as well as in the near ancestry of the dam. This of course cannot be known unless the records of the milk production are kept. No breeder, whatsoever may be his skill, can produce genuine Milking Shorthorn in the absence of milk records.—Thomas Shaw in Breeders' Gazette.

COWS MOST ECONOMICAL

Much attention is now being paid to efficiency, to economical production, and to the nourishing properties of foods. The dairy cow has not only demonstrated that she can produce more human food from a given amount of feed, but that she consumes a larger amount of feed which could not be used for human food, than any other farm animal. The steer of the future may be fed more coarse feed than he has been fed in the past; or, in other words, about the same kind of a ra-

tion as the dairy cow is receiving. He will never be able to approach the dairy cow in economical production or in producing a food of such vital importance to the welfare of humanity as the dairy cow.

Jordan, director of the New York Experiment Station, found that for every 100 lbs. of digestible nutrients the cow returned 139 lbs. of milk which contain 18 lbs. of edible solids. The pig on the same amount of feed returned 15.6 lbs. of edible solids; poultry, dressed, 4.2 lbs.; the steer, 2.8 lbs.; the sheep, 2.6 lbs.

Henry says: "The cow easily leads all farm animals in her power to convert the crops of the field into human food, with the pig second, poultry following, and the steer and sheep coming lowest."

The Ohio Station estimates that only 7.7 per cent of the cow's feeds can be used as human food. Further, the food which she provides from the coarse fodders and by-products is the most refined and essential to human welfare. This we conclusively proved by the series of articles Dr. McCollum of John Hopkins University wtire for us and which we published several years ago and again last winter in our columns.

Here we have in a nutshell the reason why the dairy cow holds such an important place in our agriculture to the human race, and why no other animal can replace her.

CLEAN-CUT ADVICE ON FEED BUYING

"Feed Inspection for 1917", a Wisconsin Department of Agriculture bulletin, discusses the present problems in feed buying and lists analyses of various products being offered on the market. In opening, it deals out a concentrated portion of advice which has the additional quality of a good feeding ration of being readily assimilated.

The problem facing the dairy farmer buying feed is not, so it advises, "where or how can I buy a ton of feed at least ocst", but rather, "how can I provide for the growth, production, and maintenance of my stock at least cost".

On the proposition of buying low grade feeds the authors of the bulletin tersely remark:

"A pound of good feed is worth a ton of worthless feed, and it is more economical to pay $50 a ton for some feeds than $20 for others. Only a few days before this was written, the inspection service received a letter from a feed dealer asking about the merits of a certain feed sold under an attractime name. The dealer said there was a heavy sale on the feed because it was cheap. A look at the guaranteed analysis showed that the dealer was right as to cause unless there was a big shortage in roughage in that vicinity. The guarantee and also the analysis showed that the feed was of a low grade. Only as a lightener for heavy feeds was its use justified. Roughage is roughage. It makes no difference, so far as results are concerned, whether it comes out of a bag labeled with a fancy name, or whether it is taken from the straw pile. The farmer may fool himself, but he cannot fool his stock. Of course, all roughage has not the same value, but no roughage is a successful substitute for a concentrate."—Hoards Dairyman.

SUBSTITUTING OLEO FOR BUTTER

It has been noted many times that when oleo is substituted for butter, there are fewer pounds per week consumed. In discussing this subject several years ago in the United States Year Book of the Department of Agriculture, Dr. A. E. de Schweinitz said:

"This product (oleomargarine) was furnished to the inmates of a certain blind asylum without their knowing its character. They ate less and less every day, and finally altogether refused to use it, saying that it was undesirable. This was the natural rebellion on the part of the digestive organs to the use of a mixture of fats which was not adapted for the purpose to which it was applied. While recently engaged in an examination of samples of oleomargarine, an employee of the Bureau bio-chemic laboratory under took to substitute a good brand of oleomargarine for butter at his meals. After a few days he claimed that this had caused indigestion, and he would not use it any longer.

"Without entering upon a discussion of the process of digestion in the animal body, the action of the pancreatin appears to be most important in the emulsification of fats. An artificial digestion, imitating as nearly as possible the conditions obtaining in man, shows that butter is far better emulsified than either cottonseed oil, oleomargarine, o rsuet, and consequently more rapidly digested. The undesirability of oleomararine is proved again by the fact that in hotels, boarding schools, and public institutions where oleomararine and butterine are furnished instead of butter, there is less used."

An Ideal installed now will pay its own cost quicker than ever before

Thousands of Ideal Green Feed Silos have earned their own cost the first year on Canadian farms.

But an Ideal erected on your place this summer will pay for itself in less time than ever before. Why?

Because it will greatly reduce the amount of dry feed you'll have to provide for your stock next winter—and mill and grain feeds are higher than in many years.

And because it will enable your cows to give 20 to 25 per cent more milk—and butter-fat is bringing 40 to 60 cents a pound, as against 20 to 30 cents in other years.

Figure it out.

Write today for our illustrated silo catalogue. You've no time to lose if you hope to get your silo erected in time to take care of your 1918 corn crop.

MONTREAL PETERBORO WINNIPEG VANCOUVER

GOOD FEEDING AND GOOD COWS ALWAYS PAY

A wise, close thinking Wisconsin dairyman recently wrote us to this effect:

"Talking about the high prices of feed I will say that I never saw the time yet when feed prices were so high that a good cow would not pay a profit on what fed she consumed providing she was fed to her full capacity. I might say further that I never yet saw feed so cheap that it paid to keep a poor cow."

There we have it; the true line of measure between cows and feed. It sems to be quite a difficult thing to bring the average cow owner up to that standard of judgment and action. But it is a safe rule to follow, one that the cow owner can trust almost with his eyes shut. The wonderful spread of the cow testing associations in Wisconsin testifies to the fact that there is a large increase of farmers who are being converted to that idea. Once more we state the rule. It always pays to feed a good cow up to her capacity of production no matter how high priced feed may be. It never pays to keep a poor cow no matter how low priced feed may be.

There follows a third conclusion: It will pay richly to test the cows in the cow testing association and find for sure which are the good and which the poor cows.

FARMERS AND BREEDERS

Who wish to keep their horses and cattle strong and healthy, should always have on hand a supply of

OMAZON

The Canadian medicinal stock food for Horses, Cattle, Sheep, Hogs and Poultry.

It will help to economize on feed and owing to its sovereign tonic and curative virtues will keep the stock strong, healthy and free from many ailments.

Order from your dealer. If he hasn't it in hand, he will be pleased to obtain it for you.

WHEN BUYING HERD SIRE GET A GOOD INDIVIDUAL FOR BREEDING TELLS TALE

The sire is half the herd. Sometimes one is inclined to think he is the whole herd. He makes or unmakes your herd. Show me your progeny and I'll tell you what kind of a sire you have. Go into any small town and look at the kind and quality of horses tied to post, railing, or in livery stall and if you are any judge you can tell what kind of stallions are in use. Watch a community unloading pigs from sled or wagon preparatory to leading in car, and if you are a judge of hogs you have a pretty fair idea of the character of boars in use. Note the quality and kind of cattle shipped and without a doubt you know a good deal about the bulls used in the country. Incidentally, you know something of feeding methods.

Why? Because blood counts. Because breeding will tell its tale, in uniformity of get of well-bred sires, in uniformity of color, of shape, of vitality, of breed characteristics, in everything that makes for improvement. Lack of blood, lack of breeding also counts. It counts as much as blood in lack of uniformity. With a bull of no breeding you get all colors, all sizes, all shapes, all degrees of efficiency. No improvement, no nothing. What it does get is disappointment. Then why not buy a good sire?

If breed does not count, one ought to find the best stock in the world where good principles of breeding are not followed. One ought to find a Jean Armour, a Rauwerd or a Duchess Skylark Ormsby in among common cows in a common ill-bred herd. One ought to find a Dan Patch once in a while where light horses are bred yet no attention to breeding, to feeding, to selection is given. Do we? Are the great sires of the Holstein, Guernsey, Ayrshire, Jersey, Brown Swiss breeds with offspring prominent for their known production, a matter of chance? Certainly not. Corn production of one hundred bushels and over would never have been reached if corn had not been bred up. Pigs weighing one thousand pounds and more are not the result of using a poorly bred, poorly selected sire. Carnot, that wonderful Percheron stallion, was the greatest son of the greatest son of famous sires for five generations back. They knew when he was to be foaled that he would be no mediocre horse. Breeding does count. Blood, concentrated along definite lines with a definite purpose in view, must count. It counts most through the good herd sire.

In buying a herd sire it is certainly wise to buy a pedigreed sire. Even if you have only a grade herd or a herd of mixed breeding you are safer to buy that kind. You then at least know that the blood of such a sire is pure. Each of his ancestors is on record as being of the same breeding. The ancestral blood may have been good or bad, but at least you have noted mixtures of distinctly different purposed individuals; as, for instance, a beef blood mixture in a dairy herd sire, or trotting blood in a draft horse sire. You have not only the word of the man you buy from, but you have the word of the association on whose books he is recorded and that in turn is backed by the thousands of breeders whose interests are centred in keeping blood lines pure and improving same. "Just as good as a pure-bred," or "he is a pure-bred but he has not papers," should not go unless you know that his dam and sire were registered and you were certain of his identity as their son.

But, do not buy a name. Pedigree does not make him. The word "imported" does not make him. Some people lay a great deal of stress on the fact that he had been "shipped in." That doesn't make him. "I bought him from M——". That doesn't make him. Pedigree counts, imported if from a good family counts, if bought from a breeder of repute counts. It counts more when you have to sell him or his progeny that he will count to you. These all count, but along with that you must and should buy a good individual. Some men can afford to buy pedigree and family name. Quite often such animals make good but, for you, don't take a chance.

When you buy, buy health and vigor first of all. You can not afford to buy a sire which will impair or weaken the vitality of your herd. This cannot be stated too strongly. Susceptibility to disease, hereditary physical weakness—avoid as you would the devil. It spells disaster. The full constitution, heart girth—large, in other words—the full, bright eye, the vigorous, alert, active, appearance; those are the things to look for. Don't come away without them. A good, vigorous, strong, healthy herd sire is what you want. Then get that kind to head your herd, be it common cow, grade or pure-bred.

Buy masculinity. It is a male you want. Be sure you get it. A good bull should stand squarely on his four feet and impress you with his power. He fears neither you, the devil, nor Kaiser Bill. All he asks is to get a chance at some other bull and he'll show you he is master. He is every inch a sire. Masculine head, broad muzzled, large nostril, bright, large eyes far apart, thick horn, backed by a full back and crest with a bellow that is as masculine as his appearance would indicate; not coarse withall; refined power; a well balanced fellow with straight back; wide, deep ribs; long, wide, level pelvic arch; a well hung scrotum with rudimentary teats of good size placed far apart. Masculinity in a sire means prepotency; it means that you will get in numbers what you buy as an individual.

Then, too, buy size. Do not buy the son of an immature heifer, a heifer that has not attained some maturity of body before being bred. A Holstein bull ought to weigh a ton when mature and as a year-old or two-year-old he should show that he will. Growthy—that is the word. The dam must be large, likewise the sire. Your stock will get small enough, quick enough, without helping it along with an undersized bull from undersized parents.

Buy Size, Buy Masculinity, Buy Health, Buy Production.

One may buy health, masculinity, size, and yet not get what you are after. You want a uniform, vigorous, well proportioned, attractive herd that will produce. Hence, you will have to buy from a producing herd, from a dam that is an economical and large producer. Here is where records will help. The seven-day record is good, the thirty-day is better, but the only record that ought to go with you is the record for the year, better still for years. The sire transmits this power from dam to daughter, the power to produce more milk on less feed. Then, too, one should see that the dam is not a tough milker, that she has a well balanced udder with teats well placed, one on each corner, of right size, far apart. One must see that she is feminine in character, but has the vigor, size, and form perfection you want in your herd. The better your herd, the more particular you must be. The better the breeding, the quicker your herd will be among the best. Can you afford to take the time to develop your own herd in efficiency, in form, when by buying a good herd sire you can take advantage of patient, careful, systematic breeding of men more skilled than you. Time is too short. So buy as good a sire as you can buy. It will pay.

And when you do buy one, take care of him. If he is half the herd, he is entitled to the best stall in the barn,

Road Debentures

Two Hundred Thousand Six Per Cent (6%) Twenty Year Road Debentures of the Province of New Brunswick Affording a Rare Opportunity for Large and Small Investors.

—O—

The Government of the Province of New Brunswick will receive applications for the purchase of any portion of $200,000.00 twenty year six per cent Road Debentures—Price Par.

These Debentures will be issued in denominations of $100.00, $500.00 and $1000.00, bearing date 15th August, 1918. The interest payable half yearly on the 15th of February and 15th August in each year. Exempt from taxation in New Brunswick, except succession duties. Principal and interest payable at any Branch of the Bank of Montreal in New Brunswick and at the Bank of Montreal in Montreal, Toronto and New York, at the option of the holders thereof.

Investors are invited to apply at once for these Debentures either by letter or wire to

THE COMPTROLLER GENERAL

FREDERICTON, N. B.

Applications will be filed in the order received.

the best of care, the best of attention. Feed him poorly and he will loose in vigor, in size, in health, in prepotency. You don't want that. If you ever become famous as a breeder it is because you were fortunate enough to possess and use a good sire. He will make you if he is a good one. He will break you if a poor one. That is what is killing so many dairy farmers today, poor sires and poor feeding methods.

How much can you pay? Not as much as you pay for a poor one in the final reckoning. If you have but ten cows to replace with ten offspring and those give but one quart of milk night and morning more than their dams, and possibly extend the lactation period a month or two, it will mean at least 50 lbs. of butterfat. At forty cents a pound it will mean $20 each or $200 a year, or $2,000 during the ten years of service in your barn where they displace their poorer dams. How much? That is for you to say. If you buy a tried sire there is no chance. It is the herd sire you buy that will make you or break you.—J. Bower in Hoard's Dairyman.

WHY SO MANY YOUNG CALVES DO NOT THRIVE

Riding through the country in summer one sees a surprisingly large proportion of calves which do not look as if they were thriving as well as they might. Since a great deal depends on getting a good start with a calf, as well as with any other young animal, it might be well to investigate conditions and find out what is the reason for such a lack of thrift. Three things may be taken for granted as the chief causes, says E. E. Rockwood in Hoard's Dairyman.

First, we will mention lice. Usually a spring calf is kept for a time in a stable or until the weather becomes warm when it is turned out in the pasture. Even a very short time will suffice for it to become infested with parasites if such are permitted in the stable, and it is surprising how many otherwise up-to-date and comfortable farms are thus infested. Since lice and mites multiply rapidly when the warm weather comes, a calf would soon become badly troubled with them and no animal under such circumstances could possibly thrive. One has but to notice how many calves and other cattle are rubbing and licking themselves to see that cases of the kind are quite common. Lice are present many times when not suspected and a thorough examination should be given on general principles and, if found, treatment should be promptly applied. One of the coal tar preparations or sheep dips used according to directions will be found efficacious in destroying the parasites. Probably in nine cases out of ten the cause of the unthriftiness will be located without going any further.

However, there is another thing, especially in the market milk secretions, which contributes to the underfed, unthrifty appearance of the calf. This is an unsufficient allowance of milk. Tempted by the ready cash which it commands, owners cut down the milk ration often almost from the very first and substitute something else. When a calf becomes older and can assimilate other food, this substitution will do no harm. However, there is no substitute which can successfully take the place of whole milk at first and two weeks is none too long to feed this before replacing a part of the ration with that from which the cream has been removed. For best results a generous ration of skimmilk should be fed for months, the longer the better. All summer is not too long for the spring calf to get its mess of separated milk morning and night and this should be supplemented all along with a grain ration of a kind to promote growth, such as bran, middlings, oats, or oil meal, with a little corn, either whole or ground; in the latter case, not placed in the milk but fed dry. Calves require some salt also but should be permitted to help themselves rather than have this added to their grain. Fresh water should also be supplied regularly. As a rule, pasture which calves get is not very nourishing and many times they will do better confined in clean, loose stalls where they are not exposed to flies and extreme heat. The calf pasture, too, is frequently shared with hogs, a condition not conducive to thrift. Weeds usually abound and little food of any value grows where maintained year after year as a joint feeding place for different kinds of live stock. Kept in a sanitary stable and provided with clean clover or alfalfa hay, in addition to its milk, a calf will do better than in the average pasture.

Still a third factor contributing to unthriftiness in the summer calf is bowel trouble. The digestive organs are weak in the young animal and easily disturbed. I have known a bad case of indigestion caused solely by an overfeed of milk. This required weeks to overcome when the calf was off its feed and suffering from scours. Good, healthy calves should have the allowance carefully watched until they are well established, else they will overeat and do themselves harm.

In these days of stress and strain so much depends on our live stock that each individual should watch carefully to see that nothing is neglected which can contribute to the cause of winning the war by making the very most of every bit of our resources. It is certainly poor business to allow young stock to depreciate, become undersize, and lack in thrift when simple precautions and insufficient feed will keep them growing. A stunted calf or pig or colt will never make the animal it would have been if properly nourished. So it proves to be a costly mistake to scrimp the young calf on its natural nourishment or to allow it to become the harboring place for parasites which sap its vitality and hamper its growth.

CHEAP FEED FOR THE BROOD SOW

1. Too little value is placed on cheap feeds. Clover and alfalfa hay are very much relished by breeding rition constituents, protein and mineral matter. Roots are nutritious and insure health. Vegetable, fruit, and kitchen refuse materially reduce the meal requirement.

2. Exercise is too often overlooked. Confining a brood sow in a small pen is bad treatment and usually accounts for dead pigs. A much better plan is to give her access to the barnyard. The horse manure pile will prove attractive and valuable to her. If she cannot visit the manure pile, some horse manure may be placed in her pen. It may add to her comfort; in any case it will interest her and cause her to take at least a little exercise.

3. Mineral matter in the feed during winter is conspicuously absent. Such feeds as clover and alfalfa will supply some, but not enough. Earth, salt, lime, charcoal, and ashes are all rich in mineral. Some of them, if not all, should be supplied.

4. Wheat bran is a good feed for breeding hogs. A little of it is all right for young pigs, but it is not a fattening food and should not be used in any quantity for fattening hogs. Shorts is one of the best all round feeds, but should not be depended upon entirely, particularly in the finishing period.

IMPERIAL SERVICE

If you are in doubt about the proper lubricant, *ask the Imperial Oil man.* He will give you courteous attention and sound advice on your lubrication problems. That is part of Imperial Service.

FARM MACHINERY AN ASSET ONLY WHEN IN USE

YOU get no return from your investment when your farm machinery stands idle. Delays caused by broken parts or worn out bearings are costly. Many times these delays can be traced to improper lubrication. *Correct* lubrication is an important factor in keeping your machines in shape for full service.

You take no chances when depending on us for lubrication advice. We know and will recommend to you the correct Imperial Oil for every lubrication requirement. We can advise you and can supply the correct lubricant at our many stations all over Canada. There is one near you.

Every Imperial lubricating oil is sold in steel barrels and half-barrels—convenient and economical. There's no waste. You use every drop you pay for. You are sure it is uniform and clean.

THE HORSE

WATER FOR TEAMS

A surprising difference in heat resistance could be noted among farm teams during the recent very hot days. On some farms the horses worked righ along without let-up; on others they appeared fagged and they evidently suffered from the heat. One of the conditions commonly present where the teams worked well was adequate provision for watering the horses. The water was pure, cold and plentiful. Generally it was offered frequently. In many cases the horses had free access to water during the night.

When weather is very hot a horse at work sweats out of his body a great quantity of water during the day. It is impossibye to drink enough at the usual four waterings a day to fully replenish the water content of the body tissues and organs. As the hot day draws to a close the hard-working horse gets more and more in need of water throughout the body. He craves it. When he comes in at night, tired and thirsty, his capacity for holding water limits the amount that he can drink long before a balance between water and soldis in the body is reestablished. Perhaps the driver drags the thirsty horse away from the trough before he is through drinking because he fears too much water will be taken in and a case of colic be the result. Another chance to drink is planned but perhaps forgotten. More frequently the horse is taken away from the water tank too soon because his pause in drinking to catch his breath and allow the water to pass through his stomach is mistaken for the signal that no more water is wanted.

In well regulated city stables this difficulty is overcome by watering the horses again after supper. This is seldom done in the country unless the horses are turned out for the night. Really it is better for the horse to turn them out where they can drink at will during the night. They are wonderfully refreshed by this practice just as men are taken several times after quitting the field on a very hot day, winding up with two or three glasses of water just before going to bed. Even where horses are not pastured at night they derive great benefit from resting and eating their hay in the barnlot with access to water. In a lot not too small there is not much danger if tired work horses injuring each other in summer. Many outfits spend the nights thus during early summer, and after about this time of year or a little earlier, when the grass gets more mature, they are turned onto pasture at night. The plan works well.

In very hot weather, particularly at harvest time, some of the most efficient farmers haul a barrel or two of water to the field and the horses are watered once or twice during each half day. Those who follow this plan assert that the horses will then do far more work in hot weather than if watered only morning, noon and night. Some accounts are related of marvelous endurance and big days' work accomplished under excessive heat by horses that had water given them frequently during the day. The only objection to it is the inconvenience. But then, it is inconvenient for any one or any horse to work in the hottest days, so we might as well accept as desirable any means of accomplishing results and safeguarding the health of teams.

It is not thirst that allows a horse to be overcome with heat. It is a weakened condition of the system. Too litttle water is a common cause to this decrease in vitality. A horse like a man, craves water more than anything else in hot weather, and that of itself should be sufficient proof of the importance of plenty of pure fresh water.

HOW TO DETECT LAMENESS

A horse is lame when during action one or more of his limbs acts abnormally by reason of pain, weakness, inefficiency or obstruction. Lameness also may be a symptom of disease. Motion is necessary to make lameness manifest; but certain indications of lameness may be exhibited by the horse in repose. To detect lameness the horse should be examined when at rest and then in motion. The examiner must first determine which leg and then what part of the leg is affected.

Let the horse stand in a level place. If sound he usually will stand squarely on all fours. Departures from this natural position suggests lameness. If a front foot is placed forward, so that it is relieved of supporting its due share of weight, this act is termed "pointing" and indicates pain and lameness in that foot. If each fore foot is pointed in turn, both may be lame. If both feet are pointed at the same time they are similarly affected and lahinitis (founder) is the probable cause. Severe pain may cause a horse to stand on three legs. One foot is held off the ground, temporarily or continuously, according to the severtiy of the pain pressure. Two fore feet may be alternately elevated, or the hind feet may be similarly rested or advanced under the body.

Knuckling, cocking or bending forward of the fetlock joints when a horse is standing at ease may denote pain, but this posture of the hind fetlocks sometimes is noted in a practically sound horse. Permanent knuckling is suggestive of lameness. If the heel is raised, probably pain is present in the back parts of the foot, as is the case in corns or navicular disease. If the horse rests its weight on the heels there is pain in the front part of the fooot, as in acute founder or ringbone. Frequent shifting of the feea when standing at rest may indicate lameness but this act often is due to temporary leg-weariness and foot-soreness from a hard drive.

Cracked, contracted, ridged, enlarged, flat, steep or disturbed hoofs, pasterns abnormally upright or too much slopd (broken down), tendons bowed, filled or thickened, knees bent forward, elbows pointed outward, muscles wasted (atrophy or sweeney), shoulder held upright and leg hanging or pendulous, evidences of blistering, firing or settons swollen, enlarged, puffed or crooked joints, bony growths, sores and wounds, or bulging of parts that should be straight, as buck shins and curb, are other symptoms possibly indicative of lameness. Abnormal displacement of the feet or joints of the hind legs are as characteristically suggestive.

Lameness may become apparent when the horse is made to move over in the stall. Spavin lameness and other acute conditions of the hock joint cause the animal to bear the weight on the sound leg and hop with the lame one. On backing out of the stall chorea (St. Vitus dance, shivering or coampiness) may cause sudden jerking up of a hind leg, spasmodic elevation of the tail and twitching of that member and the muscles of the flank, thigh or quarters; or backing up may be evidenced by dragging of the fore limb.

The horse, having been examined in the stall and when standing still, next should be walked away from and to the observer, then slowly trotted away and back. When walked anad trotted free action should not be hampered by a short halter rope. "Bridle lameness" may be induced by trotting the horse with a short rein, thus inclining the head and neck towards the man and causing undue weight to be put upon the fore leg of that side. Slight lameness seldom is seen when the horse walks. Trotting brings it out, as it increases weight upon the members sustaining the body. When walking three members are always upon the ground, the feet coming up one at a time. During the trct two feet are off the ground at the same time, the horse progressing by diagonal legs. Thus lameness of an unsound member will be accentuated by the greater concussion of trotting.

If lameness is present in a fore leg the horse will throw the weight upon the sound leg, favoring the sore one, and the head will nod or droop toward the sound leg. If lame in a hind leg the hip of the sound side droops and there is a corresponding rise of the lame quarter. If the observer nods his head, keeping time with the horse, he will more easily determine which leg is affected. The veterinarian may in doubtful cases inject cocaine or eucaine hypodermically over the nerves in deciding whether the lameness is located high or low.

Chronic lamenss of a fore leg may occasion seeming "cross lameness" of the diagonal hind leg. Lameness of a hind leg also may cause the horse to bear undue weight upon the opposite fore foot. If both fore feet are lame the steps are short, the pasterns upright and the action stiff and stilty. The horse goes sore or groggy. If the toes of the fore feet turn upward during action, chronic fonder may be suspected, or the heels may have been abnormally lowered by prolonged abuse of the shoer's knife.

The beginner, if puzzled, may trot the horse upon soft ground and be guided to the lame leg by the shallow impression its foot makes upon the ground. The expert will note the

Barrett's
EVERLASTIC
"RUBBER"
ROOFING

You can see the quality of Barrett's Everlastic "Rubber" Roofing as soon as you open the roll.

The best of materials, the utmost skill possible in manufacture, and the experience of over sixty years in making high-grade roofings goes into every roll.

Thousands of rolls of Barrett's Everlastic Roofing have been used by the Canadian and U. S. Governments, the leading railroads, and the largest contractors in the country. Dollar for dollar, it is the best "rubber" value obtainable today.

Don't waste your money on poor roofing that will need to be renewed in a short while. It will pay you better to insist on Barrett's Everlastic and see that you get it. The name Barrett is your guarantee against disappointment. You will find it on every roll of the genuine Barrett Roofings.

The Recognized Specific of Diseases of the Horse

A sovereign remedy in powder form which cures, Coughs, Heaves, Colic, etc. It strengthens the work horse as well as the race horse, and enables them to do more and better work. It has been successfully prescribed by many veterinarians notably by Dr. J. D. Duchene, in many critical cases, where results have proved remarkable.

A 50c box will be sufficient for six days' treatment.

DR. ED. MORIN & CO., LIMITED, - - Quebec, Canada

slight hitch, impediment or "dwelling" in the flexion and extension of a limb. decide whether there is supporting or swinging leg lameness, and by anatomical knowledge and extended experience make a correct diagnosis, often impossible to the layman. Trotting upon a hard road causes aggravation of foot lameness. Soft going may accentuate high lameness. Turning the horse sharply in one direction and then the other tends to make obs ure lameness more apparent.

The symptoms of chorea often may be noticed when the horse is turning to come back, after being walked or trotted away from the observer. Chronic springholt is characterized by rythmic jerking up a hind leg. Often it affects both hind legs and occasionally is seen in afore leg. In navicular disease and spavin lameness the horse starts off lame and warms out of it with exercise. The toe of the shoe is worn down. Ringbone lameness aggravates with exercise, causes an unnaturally long step and the horse goes on his heels. Lameness from splints sidebones or corns becomes worse with work. The foundered horse goes on his heels, becomes lamer with exercise, but improves when going down hill. Navicular disease lameness increases when the horse trots down hill.

Swinging of the leg outward indicates shoulder or hip lameness as does dragging of the toe and difficulty in stepping over an obstacle. Pronounced dropping of the stifle is seen where wasting of the muscles of the stifle and thigh has followed acute azoturia. A turned-up toe indicate breaking down or rupture of the back tendon, while knuckling may indicate thickening and shortening of those parts or the presence of a high ringbone.

Before finally deciding the seat of lameness in any case, the foot should be carefully examined, no matter how plainly the symptoms may seem to point to some other part. If this is made the invariable rule, many errors in diagnosis will be avoided. A leather sole or rubber pad may cover a diseased condition and a bar shoe, or other special form shoe, always should arouse suspicion. Give no flash opinion as to the seat or cause of lameness. "Least said is soonest mended." Even the greatet expert may require hours or days in arriving at a decision.—Dr. A. S. Alexander, University of Wisconsin.

PATIENCE WITH TEAMS

With drawling word of command and leisurely manipulation of the reins a man with four horses to an 8-foot binder cut 17 acres of wheat per day through the blistering hot days of harvest. There was no hurry or excitement and the four horses kept slowly and steadily moving along at the edge of the stanading grain, always cutting a full swath and leaving the bundles nicely laid in straight windrows. The man explained that there was no use to hurry. Four horses were all he had, and they had to stand the strain. He did not dare hurry them, for as it was they kept about as hot all day as it was safe to have them. A crack of the whip or a yell would have started an extra flow of sweat and made them puff all the faster as they would try to hurry along. Then a stop to rest would have been necessary.

Men nearby who had plenty of horses drove faster, changed teams frequently and sometimes drove during the noon hour, but still most of them only cut about 20 acres per day. With twice as many horses and lots of extra work changing teams back and forth they got very little more done. Hurying beyond a natural hot-weather speed, their horses quickly got hot and kept getting rapidly hotter. The urging of the drivers to get the extra speed served to excite some of the horses and bring out a lather of sweat immediately.

The result was a good demonstration of efficiency and inefficiency with teams in hot weather. The patient policy was the most productive. Even in cooler weather the contrast is similar though less striking. The driver who is patient and pleasant and allows his team time oo turn and to move when told accomplishes much in a day if he keeps going. It is the stops that kill time. Five to ten minutes rest wastes th etime a team would take to travel across one side of a square 40-acre field. When tw obinders are cutting on the same land the one behind can hardly catc hup if once set back by a few minutes' delay. Few men realize how fast time flies when the team stands still or how far a team travels in a short space if time.

Plenty of snap is a good attribute in a farm hand, provided he keeps it under control. In hot weather one's temper needs a special guard kept over it. Slow, sure, steady motion is what performs work with the least waste of energy and we must keep within those bounds when the sun is scorching hot.

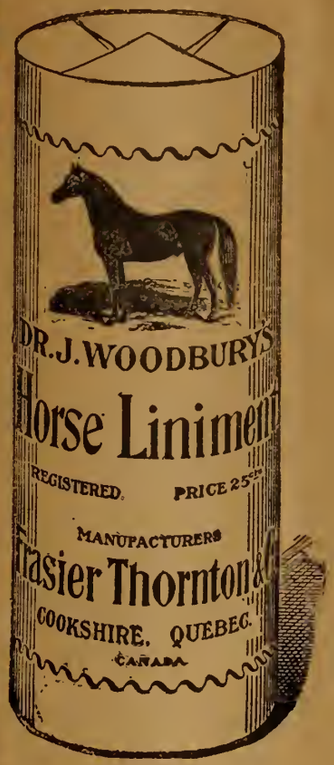
Patience with teams pays the whole year around. The conservation of a horse's energy by a careful driver saves feed, keeps the animal in good flesh and helps to prevent shoulders and neck getting sore. Then there is more power, stamina and ability to turn out good work all the time and big work in an emergency. The common tendency of farm hands nowadays to slam a team through in order to finihs a big day's work by the usual quitting time is hard on horses. It is far better for the team to take an extra hour to hake the long trip instead of hurrying beyond a comfortable gait. Extra speed always requires an extravagant expenditure of energy.

WHY PUREBRED STALLIONS

Horseman have always been ready to concede that purebred stallions have sired larger and better horses. In spite of that there have been and yet are quite a large proportion of grade and scrub stallions in service in all sections. The men who have patronized those inferior stallions must have a reason for so doing or else it is necessary to show them in definite statements of dollars and cents that their practice is in error. In order to secure such definite facts the Indiana Stallion Enrollment Board has conducted a survey in a number of counties in various parts of the state. In this survey the acutl prices received by farmers for their horses were tabulaed. Comparison was made beween he selling price of horses sired by purebred stallions and the selling price of horses sired by stallions not purebred. The result was overwhelmingly in favor of the purebred stallion in that his offspring sold for an aver of $76 per head more than the offspring of stallions not purebred.

Putting it on the basis of the service fee paid we find that if it costs $5 more to patronize a purebred stallion it pays well to spend that extra amount, because the difference in selling price of the offspring will return the $5 and interest at the rate of 1.420 per cent.. If the service fee is $10 higher for the purebred stallion there will be returned a clear profit of $66. or 660 per cent. upon the $10 invested.

Pronounced as these figures may be they are scarcely as marked as is the contrast conditions in localities where purebred stallions prevail and in localities where there are few purebreds. In sections where purebred stallions have been used for many years the country is sold out of good big geldings. In sections where purebreds have not beeen used there are horses that are begging for a market. The figures are doubtless more favorable to the offspring of the grade and scrub than they should be. It was found in the survey that quite a large number of inferior animals were absolutely not wanted by the market. If a zero valuation had been placep upon those unsaleable animals and this included in the average the difference would have probably been twice $76 in favor of the purebred stallions.—H. E. McCartney in Breeders' Gazette.



Horsemen, Attention !

Mr. Farmer---

We Believe You To Be Fair

We Know You Realize That There Are Two Sides to Every Story and That a Fair, Square Hearing is Every Man's Right

So, We, the Canadian Manufacturers' Association, ask you to read our views (published at our own expense) on the subjects of Tariff and Co-operation as presented in an address by Mr. S. R. Parsons, Retiring President of the Canadian Manufacturers' Association in Convention before this body, at Montreal, June 15th, 1918

"Speaking broadly, Canada must choose between the Tariff with Manufacturers on the one hand, or free trade without manufacturers on the other; the issue cannot be dodged and should not be clouded."

"The Tariff is not simply a matter of give and take between manufacturers and farmers. What about labor? What about railway companies, the merchants, the financial institutions, the people at large? The Tariff affects everybody".

THERE are two subjects of sufficient importance to claim our particular consideration this year and upon which we should focus our attention. I have, therefore, concluded to disregard all precedent, which, if followed, would constrain me to deal in a somewhat discursive manner with many matters of interest to our Association and the country at large.

The first question has to do with the relationship between employers and employees, and the second the problems of the tariff, particularly as affecting manufacturers and agriculturists. In discussing these topics, I am sure you will agree with me in saying that we should lay aside any ingrained prejudices or conclusions which would prevent us from reaching decisions that are unselfish, broadminded, and national in scope. As men holding a high and important place in the nation's affairs, we should feel that unless we approximate in spirit many of our members, as well as hundreds of thousands of others who have without reserve given themselves freely to the service of the country in defence of the things that we all hold dear, we are disqualified for dealing with important interests which have to do more particularly with the nation's life at home. From an intimate knowledge and association with the manufacturers of Canada, far and wide, I know that as a body they are characterized by the highest ideals of citizenship and service.

Capital and Labor."

First, then, let us consider the question which is usually dealt with under the heading of "Capital and Labor." We have been learning many things during the past four years and while all sorts of doctrines, theories, and even fads are being put before us which are more or less impracticable in character, yet it would be a great pity if the fine idealism which is being preached could not be turned to useful account as far as possible. The thing which we call democracy is revealed more in spirit than in organization or regulations. If democracy is going to be anything more than a label on an empty bottle, it must characterize our human relationships and actions. We have, perhaps unconsciously, ignored to some extent the human element in giving effect to the relationship existing between employer and employed. In the old days when in small shops the so-called "master" worked with his men, often at the same bench, and each called the other by name, there was continuous friendly intercourse which resulted in producing good relations throughout. Afterwards, with the introduction of machinery, there was brought about an industrial revolution. Instead of the small shop with few workers, there was the great factory, with many hands, so that is soon came to pass that empoyer and employee did not often meet or even know each other.

The result in many cases has been that the workers came to look upon themselves as part of the machinery of the organization to be used solely in the interests of the producing capacity of the business. It was quite natural, therefore, to expect that disagreements would arise between the two chief interests involved that have led here and there to occurrences of which neither side could possibly be proud. We have now come to see that just as the human body cannot do its best work unless the integral parts are acting together, so in the case of our great industrial system, there must be a living spirit of working together in order to complete service. We have had, perhaps, more or less of the external form and have boasted too much about the body of democracy when having little of the soul. Looking around us, and especially in Old World countries, though not unknown even in Canada, there are armed camps of Capital and Labor. I have no hesitation in saying that these should find some method of union. These two classes must stand together in their own interests. There must be a meeting ground where antagonism and suspicion shall not dwell. The situation at present is aptly described by the quotation:

> "In the world of industry, employers explain too little, employees exclaim too much, economic teachers proclaim only a bias, and politicians only declaim. There is no one to interpret—no, not one."

Better Relationships.

Now, the question is as to how to bring about a better relationship. No one will question the advisability of trying to regain an attitude akin to that which prevailed in the seventeenth century, when there was a glory and a pride in trade and craft, which has been largely lost out of our industrial life. What a day it would be if we could make a song of our work instead of a dirge of our grievances! Capital, on the one hand, must realize the duty of caring for the welfare of all those associated in industry, and Labor must be ready to co-operate to the fullest possible extent in a spirit of helpfulness. My own opinion is that each individual industry will work out its own plans applicable particularly to the special conditions governing the concern. Many schemes, some of them quite elaborate, have been brought forward in Great Britain, providing for a more effective co-operation between employers and empoyees. In the United States some plans of co-operation have already been put into effect and others are being considered. Everywhere there is the feeling that the time has come when most earnest consideration should be given to this important matter. Nearly all the plans which have been put forward carry with them the idea of representation in our great manufacturing enterprises from both Capital and Labor. In some industries a committee of ten or twelve is appointed, half of whom represent the company and the other half the employees. These representatives are charged with the duty of dealing with matters such as employment, discipline, right

of appeal, wage adjustments, and joint conference. In a certain industry employees after one year's service are insured at the expense of the company, the amount varying from $500 to $2,000; in case the employee leaves the service of the company, he takes his policy along with him and keeps up the insurance if he wishes to do so. Annuities are also provided after twenty years of service.

No one industry can be a pattern for all, as the ability to deal with such questions is not shared equally. It appears to me that it is impossible for us to develop immediately a satisfactory plan of co-operation that might suit all the different industries with their varying conditions. There is, however, no reason why a start should not be made and some headway gained. The evolution of processes must be gradual; the new heaven and the new earth will not burst upon us in a day. Personally, I am not at all afraid to trust representatives of our workmen to join in plans of co-operation in the interests of all concerned. When we think of what our men from the ranks of Labor have done in this great war, coming forward argely under voluntary enlistment, and when we realize further the valor they have displayed on the battlefront, they are not only entitled to proper recognition at home, but to a consideration of their interests, which hitherto they have not had in large enough measure.

One thing appears to be certain, namely, that where individual interest, ambition, and good work are shown, these must all be recognized by both interests in the business and properly rewarded. On the other hand, the unwilling and the inefficient must not block the path of the ready and the skilful. **There can be no universal betterment applying to each and every worker in any scheme of co-operation without individual participation, if we are to hold our own against other countries and nations whose competition we have to meet both at home and abroad.** I would like, however, to see such a spirit of mutuality and co-operation engendered that the two great classes would think together and not apart. I believe this would result in such efficiency in all our organizations that we would be able to increase our home and foreign trade, help pay our war obligations, make reasonable profits, and pay higher wages than would otherwise be possible. It should be remembered that as from the ranks of Labor a very large proportion of our men have gone to the front, so when the war is over, to the ranks of Labor they will be returned. Much as we would like to see the returned men go upon our farms, yet the great majority will naturally revert to their former occupations. They will, therefore, be a charge for the promotion of their interests upon our towns and cities and the manufacturing industries in particular. We cannot begin too soon to lay our plans for giving effect to that particular form of co-operation which will fit our individual concerns best and enable employers and employees to serve one another.

Our scond great question is that dealing with

Manufacturers, Agriculturists, and the Tariff.

More than a generation ago the National Policy was brought into existence and, therefore, the great majority of men doing business to-day in Canada do not remember the hard and trying years before its introduction in 1878. At that time the country was making little headway under a revenue tariff of 12½ per cent. Our industries were comparatively unimportant and American factories supplied us in large measure with products such as have since been made in Canada. Generally sepaking, the commercial interests of the country were languishing and our bright young men were attracted in large numbers to the United States, a country being built up and prospered under a policy of protection. We are now in danger, especially on account of the propaganda of one section of our population, of failing to profit by experience, losing our balance, and blindly yielding to the demand for undermining that which has proved to be the great bulwark of our national, industrial, and commercial life.

The War-time Tariff Truce.

It was understood, when Union Government was formed, that the agitation of the Western grain growers for the abolition of the tariff would not be continued during the period of the war. This has been denied by some of the grain growers during the session of Parliament just ended, but a newspaper report of an address by Honorable T. A. Crerar, at Winnipeg, in the election campaign states:

"The Minister of Agriculture alluded to a conversation with a farmer in Toronto the other day, who asked him:

"'What concessions did you get on the tariff?'

"I required no concessions," declared Mr. Crerar. "The Tariff is not the issue at present. I feel just as strongly on the question of tariff as any man. I have not sacrificed these views in entering a Union Government. The tariff is not the isseu at present. The great outstanding issue is the winning of this war.'"

The Toronto **Globe** referred editorially to this matter and spoke of it as a "truce"; in fact it was more or less the general expression of opinion at the time of the formation of the Union Government that tariff matters would not be referred to until the war was over. The manufacturers, therefore, accepted this view and would have respected same throughout if others had done so. We have found, however, that in the Western Provincial Legislature resolutions have been passed asking for the removal of the duty on agricultural implements as a so-called "war measure." In farmers' papers and other organs there has been carried on a constant agitation against the tariff and denunciation of the manufacturers. Grain growers have recently challenged manufacturers to come out openly and declare themselves upon the tariff question. Much as we would have preferred that there be no consideration of this question during the period of the war, as all our attention should be fixed upon our national obligations with respect thereto, yet some measure of action has been forced upon us and it is therefore, necessary to deny many of the unfair, erroneous, and misleading statements that have been made for the purpose of trying to prejudice the minds of the public against manufacturers and manufacturing interests in this country.

Agriculture and Industry Interdependent.

Agriculture and Industry Independent.

Our statements should be prefaced with the remark that the manufacturers of this country, along with all other classes, are vitally interested in the success of the agriculturists and will not be satisfied until the fullest possible measures looking to their betterment and the removal of any inequalities or unfair burdens, are accomplished. It surely is not necessary to do this, however, at the expense of other classes and at the risk of ruination of our great industrial fabric, built up with great care and national efficiency. A great Toronto daily sets forth admirably the relation of manufacturers to agriculturists in the following words:

"If agriculture is the backbone of the Dominion, industry is the sinew and brawn. Each is vitally important; they are interdependent. Progress and prosperity for one invariably means progress and prosperity for the other. Their success provides food or their failure provides famine for the people. Trade balances depend upon their activity. A favorable balance swells Canada's bank roll, and the people become prosperous and very happy under normal conditions."

Reciprocity.

We are told that especially in the West, peopled so largely with American citizens of an excellent class, there is more or less of a demand for reciprocity, if not a closer connection, with the United States, which, perhaps, is quite natural, particularly among the class referred to. While as Canadians we value more than ever our friendship with the great nation to the south of us, yet we believe we have an important part to play as an integral portion of the great British Empire and in working out our own future. When there was an agitation for reciprocity, in 1911, and which certain elements in our population are now trying to revive, the majority of the people decided against it and in favor of a continuance of our national, political, and fiscal policy and entity. As nothing has occurred since to lead us to believe that we were mistaken at that time, it is perhaps well now to emphasize our views and refresh our minds on the question by referring to what the then President of the United States thought of the reciprocity campaign and of its

"Speaking Frankly and Sincerely"

The portion of this address referring to the Tariff was given in response to a direct challenge of the Grain Growers' Guide [the official organ of the agriculturists of the West] to the President "to speak frankly and sincerely and come right out into the open on the tariff question." In its issue of June 19th the Guide says:

> "The Canadian Manufacturers' Association has had its annual convention and S. R. Parsons, the president, just retired has spoken. True to the intimation given through his recent letters to The Guide, he "came out into the open" and spoke frankly about existing differences of opinion with regard to the tariff. A digest of his speech as well as a summarized report of other features of the Canadian Manufacturers' Association convention appears elsewhere in this issue. It ought to be read closely by all grain growers, for Mr. Parsons, accepting the suggestion frequently offered by The Guide, has strongly urged that a conference between manufacturers and grain growers be held in Winnipeg some time this year. The dominant note sounded by Mr. Parsons in his address of last week at Montreal was national unity —a unity which would enable the manufacturer, the workman and the farmer to live and work together in Canada for the good of the country as a whole. This desire was expressed by Mr. Parsons in words of deep fervor, and we are told that his speech was received with great applause by the manufacturers who attended the convention."

As only excerpts from the address have appeared in the press, the Canadian Manufacturers' Association have concluded to publish it in its entirety for the benefit of the public, it being endorsed unanimously by the large Annual Meeting of the Association recently held in Montreal.

effect upon Canada as well as the United States. In a letter written at the time to Colonel Roosevelt, and made public afterwards, President Taft said:

"The amount of Canadian products we would take would produce a current of business between Western Canada and the United States that would make Canada only an adjunct of the United States. It would transfer all their important business to Chicago and New York with their bank credits and everything else, and it would increase greatly the demand of Canada for our manufactures. I see this is an argument against recopricity made in Canada, and I think a good one."

We all know that Mr. Taft is an extremely capable business man as well as politician, and he recognized at once what even a measure of reciprocity, such as was then proposed, would mean to both countries. It would thus appear that our shrewd friends in the United States saw in the proposition what some of our Canadian politicians and others were blind to. The war-time measures of reciprocity that have been created are hardly a valid argument for their operation in normal times from a national standpoint. **Surely we would not be foolish enough now to want to place our country and our national existence in the condition so well described by Mr. Taft, nor are we ready to believe that our destiny lies in a severance of Empire ties.** Already Great Britain is taking steps to bind all parts of the Empire together in closer commercial relations for after-the-war trade. We in Canada have helped to create, as well as bear, heavy Empire war burdens and this ought to be followed by our full share of peace responsibilities; in fact our national and our Empire obligations must now be paramount in our thought and plans and receive greater and more serious attention than ever in the past.

Hostility to Manufacturers.

It would appear from the propaganda being waged with such vehemence against the manufacturers of Canada that the chief view presented is that the tariff is retained solely to benefit the manufacturers and to oppress all other classes of the people, the farming community in particular; in fact one of the leaders in this propaganda in a recent article, which throughout is full of abuse of the manufacturers, commences the same by quoting from Sir Wilfrid Laurier in June, 1893, as follows:

"But I appeal to your judgment in the face of the experiment of the last fifteen years under the system which was introduced by the Conservative party, which was dubbed the 'National Policy,' to say if that system was not vicious in principle, iniquitous in its terms, and dangerous in its consequences, I say that it is vicious in principle."

Now this quotation is evidently brought forward to give the farmers of the West the view that Sir Wilfrid Laurier is the apostle of Free Trade and a non-believer in the National Policy. It would have been more honest had the writer stated that when Sir Wilfrid came into power and was in the saddle for so many years he found the retention of the National Policy, as reflected in the tariff, to be entirely necessary in order that proper revenues might be raised for the country. The writer in question further refers to the manufacturers in his "Hymn of Hate" as follows:

"It is conclusive proof that the 'infant' we have so tenderly nursed for fifty years has become a selfish giant, **as ruthelss and destructive as the one we are sending our armies to resist in Europe to-day.** Never before in the history of our country has the mailed fist of special privilege so plainly shown itself."

Trade and Tariff Board.

It is therefore, quite evident that the time has come when the manufacturers of this country can no longer keep silence, either in their own interests, the interests of Labor, or the great national interests of this country. It should be remembered that the present tariff, with changes here and there, was enacted as a great national policy, not for the benefit of any one class, but for the well-being of the nation at large. No one who is not ignorant of the subsequent history of our Dominion can say that it has not justified its existence. An enormous revenue has to be raised in any case and in no other way can the amount produced by the tariff be raised so easily and fairly as by the present methods, which at the same time incidentally give reasonable protection to our great manufacturing industries. Manufacturers feel that the tariff could and should be changed here and there, and so amended that it would apply more scientifically than it does at the present time. **For this and other reasons, the manufacturers would like to see created what might be termed "A Trade and Tariff Board"; such a Board to be composed of representative men of actual experience and wide knowledge of commercial conditions and whose broad outlook and vision would fit them particularly for the proper study of these great questions so vital to our national interests, this Board to report to the Government from time to time their findings, and if after a full and complete survey of the situation, it be clearly established that the tariff is inimical to the best interests of the country at large; nay, more than that, if it is not actually essental from a national standpoint, then, I say, "Away with the tariff."**

Not Simply Give and Take.

The time has arrived when we must all face this matter in a sincere and broad-minded fashion. It surely cannot be simply a matter of give and take as between manufacturers, on the one hand, and grain growers on the other. Labor must be consulted and considered, the transportation interests of the country (now so largely controlled by the Government) must have their say, the great financial institutions of the country, wholesale and retail business, producers controlling our mines, forests, and fisheries, are all vitally interested in the question of the tariff and must clearly have a voice as to its retention or otherwise. In giving expression to the convictions of manufacturers on this matter, we should at the same time be glad to meet the grain growers of the West and would do our part to try and bring about a conference to be held a little later in the season in the city of Winnipeg; this conference to be followed by other meetings, if necessary. We desire most earnestly to co-operate with our fellow-producers and to show them in the frankest manner our problems and to be shown by them their handicaps, in order that we may each of us see where changes could possibly be made that would be of mutual benefit and help.

Industrial Protection Essential.

We would, however, be altogether insincere and dishonest did we not state in general terms that if there is one thing more certain than another, it is that manufacturers could not possibly exist in this country without the small measure of protection which the tariff affords them. The two stand or fall together. **Speaking broadly, Canada must choose between the tariff with manufacturers on the one hand or free trade without manufacturers on the other; the issue cannot be dodged and should not be clouded.** Living alongside a populous country of highly specialized industries, catering to a home demand of twelve times as many people as we have in Canada, it would be suicidal for us to attempt to compete, or develop our new country on the basis of free trade. It is, perhaps, interesting to note that, notwithstanding the enormous population of the United States and he great home markets that are open to them, they have found it necessary, in their own interests, to retain a large measure of protection by means of the tariff. Even under the present Democratic Government, reduced schedules, the average rate of duty paid on imports of dutiable goods coming into the United States for the year ended June 3th, 1916, was 30.67 per cent., while in Canada, for year ended March 31st, 1917, it was only 23.78 per cent., so that our own tariff is approximately only about seventy-five per cent., as high as the American tariff on dutiable goods. The War Tax of 7½ per cent., although added to the cost of imported goods, free and dutiable, was not proposed or desired by the manufacturers. It would appear, therefore, that those who complain of our high tariff walls have not full knowledge of our comparative position in this matter. It should be remembered that manufacturers pay heavy duties on much of their imported raw material; for instance, a large machinery-manufacturing concern in Toronto have advised me that while the tariff on their finished article would appear to give them a protection of 27½ per cent., yet their figures over a number of years show that the average rate of duty they pay on their raw materials is 25 per cent. **The protection to the manufacturer in this particular case, as in the case of very many other lines is, therefore, reduced by the amount of duty paid on the raw materials, leaving only an extremely moderate margin of actual protection.**

Honourable Chas. A. Dunning, Canadian Director of Production, is quite too good a business man not to see very clearly that even the removal of duties on agricultural implements for the farmer means that much additional burden of taxation to the population as a whole. In making his report covering the proposed removal of duty on agricultural implements, he stated he was "not concerned with questions of tariff reform, federal revenue, qustions of permanent fiscal policy, or the age-long issue between free trade and protection." Just so; if these important national considerations may be completely ignored, the whole question is extremely easy of solution. Be it remembered, though, that the two million dollars said to be raised yearly from duties on agricultural implements, if not so produced, would have to be shouldered by the people at large.

Should the Burden Be Shifted?

At this particular time in our national history, when employment for returned soldiers is going to be a matter of paramount importance, and when the largest possible revenue must be obtained in all directions to carry our gigantic war debt, the question may fairly be asked: **"Is the farming industry languishing to such an extent that in order to help it out, there must be destroyed, or even impaired, its fellow-producer, the manufacturing industry of this country?"** In fact, the weakening of the latter from our standpoint would mean partial destruction of the former. However, perhaps some figures and statements sent out by the **Grain Growers' Guide** (the official organ of the agriculturists of the West) to prospective advertisers, would help to make clear the question as to the condition of the farming population. It is stated that, based upon the figures for 1917, there will be 60,000 motor cars purchased in 1918 in the three Prairie Provinces, having an average value of $1,000 per car, making an investment of sixty million dollars, and that another ten million dollars' worth of accessories will be purchased. It is further stated that while in the United States the farmers bought forty per cent. of the cars sold in 1917, the proportion sold to farmers in Western Canada was twice this figure. It is further stated that "Western Canada, and especially the farmers of Western Canada, should, therefore, be the best prospects for your sales efforts in 1918." Another significant statement reads:

"A recent investigation, conducted by the **Grain Growers' Guide**, into nearly three hundred districts in Manitoba, Saskatchewan and Alberta, confirms emphatically the oft-asserted claim that **nowhere, and with such unanimity over such a wide area, is nature so bountiful or is the return per capita from farm life so profuse as in Western Canada.**"

"The following data is taken from this investigation:

Average size of farm.....	382 acres
Number of farms owned....	92½%
Number of farms rented....	7½%
Average acreage under crop	195 acres
Average value of farm holdings	$11,010
Average number of persons per farm home.....	5

"The wealth, as indicated above, is concretely illustrated by the official list of automobile licenses issued in Western Canada in 1917. The average for the Dominion of Canada as a whole is one auto to every fifty-seven people. The average for Western Canada (Manitoba, Saskatchewan, and Alber-

ta), is one auto to every twenty people."

Value of Cereals and Other Crops.

The figures given also emphasize the fact that in 1917 the cereal crops alone averaged in value per each farm $3.725, and that the average capital worth (land, buildings, machinery, live stock), was, as stated above, over $11,000, and that the average capital worth of the Grain Growers' Guide subscribers was $25,878. Taking their own figures of the average value of farm holdings and the average returns for the past three years, it shows that the cereals alone, without counting any other crops, have produced thirty-two per cent. per year upon the capital. There are many other extremely interesting and very satisfactory figures and statements given, all showing the great progress the agriculturists of the West are making. Now, in addition to the cereal crops mentioned in the Grain Growers' Guide circulars, we have figures issued in a bulletin by The Nor'-West Farmer, taken, it is stated, from final crop and live stock reports of the Provincial Department of Agriculture in Manitoba, Saskatchewan, and Alberta. A study of these reports gives the total value of farm-products, other than cereals, at a little larger figure than the total value of all cereals. It is fair to assume, therefore, that on the average all the expenses of farming operations would be more than met by the production of other than cereal crops, whether such products were sold or retained to add to the farmer's capital. This, then, would leave at least the profit on cereals as net returns, and I do not hesitate to say, after careful calculation, that it would be quite double the average net profits of manufacturing during the same period of three years.

The first year (1915) was disastrous, generally speaking, in manufacturing, and while the last two years have been unusually profitable in many lines, yet in others war conditions have brought paralysis. No class in Canada, however, rejoices more in the prosperity of the farmers than the manufacturers. We realize that unless producers in all classes in the country, whether engaged in farming, manufacturing, mining, fishing, lumbering, or other forms of industry, are prosperous, it is utterly impossible for the country as a whole to progress as it should. It would appear, however, from the figures given by the agriculturists themselves, as quoted above, that just now is not an opportune time for them to ask other classes of the population to assume burdens of taxation which they would like to be relieved of.

It is interesting to note that the total number of farmers in Canada holding ten acres and over is 633,748, or about equal to the total number directly engaged and employed in manufacturing.

Industrial Statistics.

Now, in order to ascertain what the National Policy has done for Canada, and is doing in the building up of our great national interests, it might be well to refresh our minds with some statistics. In the year 1915 returns show that the total number of people engaged in manufacturing on salary and wage-earners was 514,883. If we consider the munitions-making and other industries, in which women are now largely employed, we might fairly estimate the total number to-day as being about 650,000. If we multiply this number by two and one-half we should probably reach the total number directly dependent upon the manufacturing industry for their livelihood, making 1,625,000. If we add to this total the number of people who indirectly make their living on account of the total industrial dependents, we should add from twenty-five to fifty per cent., the number varying according to conditions governing different localities. This division would include farmers and truck gardeners, railway (steam and electric) workers, banking interests, civic employees, butchers, bakers, storekeepers, caterers, etc., etc. Adding only twenty-five per cent., this would give a grand total of over two million persons. The total capital employed is estimated at two and one-half billions. The total exports of manufactured products last year was $682,521,000. A comparative estimate of our main products for home and foreign consumption for the year 1917, according to the "Canadian Annual Review," is as follows:

Manufactured products	$2,000,000,000
Field crops	1,100,000,000
Dairy products and live stock	1,300,000,000
Forest products	176,000,000
Minerals	200,000,000
Fisheries	34,000,000
Eggs, fruit, etc.	40,000,000

It might be interesting to try and figure out what it would mean in the case of a great manufacturing centre like the city of Hamilton to have its manufacturing industries removed. The total population of Hamilton is 106,000, having increased from 52,000 in 1900. The total number of manufacturing plants is 340; the total capital invested $110,000,000; the total number of hands employed, including office and travelling staffs, 30,000; total wages and salaries paid per year, $25,000,000. Statistics show that upwards of fifty United States concerns have located branch industries in Hamilton, representing a capital investment of about $25,000,000. These concerns, of course, would not have located in Canada except for the incidental protection which the tariff affords. Considering the extreme industrial activity at present in a place like Hamilton, calling for large numbers of women workers, it is probable that only about two and one-half times the actual number of hands employed would be directly dependent upon industry, making a total of, say, 75,000. If we add to this even twenty-five per cent. more, as being indirectly dependent upon industry, we have a total population of over 90,000 dependents (direct and indirect) for their living upon the manufacturing industries. Any interference in any large way with the tariff which now enables these manufacturers to do business would practically wipe out the city of Hamilton. What is true of Hamilton would be measurably true of many other towns and cities.

Agricultural Implements.

We might also ask what would be involved in the question of removing the duty on agricultural implements? There are approximately 160 firms in Canada making one or more lines of agricultural implements, so that the figures given below do not include many agricultural implement manufacturers who make other lines as well, nor do they include companies subsidiary to or dependent on the agricultural implement industry. The number of agricultural impelment plants proper is sixty, total capital employed $60,000,000, total wages and salaries $7,000,000, estimated number of people directly and indirectly dependent upon the implement business 40,000 to 50,000. Now, it is quite possible that if the duty were removed on agricultural implements (and it must be remembered that the rate of duty is considerably less than manufacturers have to pay on any machines imported for use in their factories), and the duties were also removed from the raw materials entering into the manufacture of such implements, a few of the larger concerns might still live on account of their large foreign export business; yet as they purchase millions of dollars worth of supplies of all sorts from other manufacturers in Canada, all such secondary concerns would be adversely affected immediately, and there would be a general weakening and tearing down of a large portion of the industrial fabric of the country throughout. Figuring the total duty paid on agricultural implements in 1916, and taking the total value of the property of the farmers throughout Canada, it means about 3½c. for every $100, or in other words a farm valued at $10,000 would pay on the average annually $3.50. This does not seem like a staggering obligation by way of contribution to the national funds. The removal of the duty on tractors, without any consultation with the tractor manufacturers, to see what they could do o help out the situation calling for greater production, and without even making provision for the rebate of the duty on raw materials imported by the tractor manufacturers, was an unfair and unjust measure. We made such representations to the Government that they finally rebated the duty charges on raw materials, but the tractor industry, where hundreds of men were employed and others in anticipation, as well as hundreds of thousands of dollars already invested, has been paralyzed, at all events for the present.

Manufacturers' Contributions and Obligations.

Manufacturers are, however, quite tired of the abuse that is being heaped upon them from interested quarters, and while it is readily admitted that there may be many schools of economists of widely divergent views, yet it is high time that a policy of standing together in our national interests be adopted, and that we should emphasize the need of common honesty and sincerity being shown in the statements that are being circulated. The profits of manufacturers, generally speaking, have been grossly exaggerated, and while here and there abnormal figures are shown (which are subsequently largely extracted by the Business Profits Tax), yet the large profits feature also applies in the case of agriculturists. The great majority, however, of these two classes, as well as of all other classes in the country, are simply making reasonable and necessary headway. Let us look at what manufacturers have helped to accomplish in the last three and one-half years.

1. Manufacturers have contributed more largely than any other class to the furnishing of men for the colors.

2. Manufacturers in large numbers have entered into personal obligations with those of their men who may return as to giving them empoyment. As this matter of employment will be one of the most insistent questions after peace is declared, it might pertinently be asked how manufacturers can fulfil their part of the compact if the fiscal policy of the country is to be radically changed.

3. Manufacturers have been called upon to assume greater burdens of taxation than possibly any other class, and especially the farming community.

4. Manufacturers have, perhaps, more largely than any other class, contributed to all patriotic funds which have been launched.

5. No class has subscribed more liberally to all Government war loans, and it must be remembered that in very many cases those so subscribing have undertaken large obligations at their bankers to enable them to do this. Manufacturers would greatly regret being placed in such a position, either by reason of removal of the tariff or taxation measures, causing strangulation of industry that would not permit them to continue such relationship towards future Government undertakings.

6. No class has supported the farming community as much in the way of helping to supply men for the garnering of the crops, and in many cases even paying the difference in wages over and above what the farmer contributed.

7. If it had not been for the manufacturers of this country the Allies would not only have been short of munitions, but the country would have gone bankrupt on account of the balance of trade being against us. This war industrial activity has been recognized by Sir Frederick E. Smith, Attorney-General of Great Britain, in the following sentence: "She (Canada) has developed for war purposes a resource of manufacturing ability of which no one could have supposed her capable."

The time has arrived, therefore, when the Government, members of Parliament, and the people at large must be fair to the manufacturers of this country and not consider their interests as a football to be kicked about by interested politicians and others, otherwise the national interests are sure to be adversely affected. The tirade of abuse has already gone too far.

Australia's Attitude.

By way of contrast, it is interesting to note that in Australia the Prime Minister, Mr. Hughes, called all the manufacturers together in conference and outlined to them a very definite scheme calling for their help and promising the co-operation of the Government for the furtherance of industry, and especially to try and secure export business; in other words, the Government of Australia is so seized with the necessity of maintaining and enlarging her industrial life that the Government commits itself to plans of co-operation that are most commendatory. In a remarkable address at Melbourne, Mr. Hughes closes with these eloquent and significant words:

"I do not hesitate to say that with proper organization we can increase the output of the primary and secondary industries very substantially. We can rapidly increase our export trade. We can place industry on a firm basis by an organization which will aid the individual producer to increase his output, find him markets for his product, and ensure transport at reasonable rates thereto. And in this way we shall reduce the burden imposed upon us by this great war, rapidly develop our resources, find regular employment for our people at high wages, and attract large numbers of the right kind of immigrants. The war has brought to us, as to all the nations of the earth, many and grave responsibilities. We must be prepared to shoulder them. We have not only to produce more wealth to pay for the war, and to develop this our glorious heritage, but we have to hold it for the Empire and for our descendants. But there is something greater. That far-flung domain known as the British Empire produces every mineral known to man and every variety of the animal and vegetable kingdoms. Its wealth is uncountable, its resources illimitable. Organized it can control the world; unorganized it must fall a victim to a more efficient nation, and its wealth pass through divers channels to alien lands. A deep and lasting obligation rests upon all the dominions to play well their part in this great plan of national organization, without which we are undone. Inexorable circumstances, patriotism, and common prudence alike compel us to adopt such a policy as will at once develop our re-

sources, increase our production, and ensure our national safety."

Great Britain and Industry.

Great Britain realizes that in order to hold her own as a nation and maintain her prosperity, she has not only to do everything possible to get hold of trade again, which she has temporarily lost during the war, but she must also put herself in a position to regain that which other nations, particularly Germany, have taken away from her during recent years, largely on account of governmental direction and help. All sorts of guilds and associations are being formed, acting under the supervision and co-operation of the Government in Great Britain, to secure the fullest measure of trade for British industries. Sir Albert Stanley, M.P., President of the Board of Trade, said recently:

"He could not help thinking, perhaps wrongly, that past Governments of Great Britain really failed to take into account the fundamental fact that this was a commercial era, and that the efficient conduct of the great industries of the country was absolutely vital to its welfare. Unless industries could be carried on with an equal degree of efficiency, unless they could produce their manufactured products at prices that would compare favorably with those of their great foreign competitors, what chance had the country of succeeding in establishing its place with the other nations of the world? He thought that the governments from now on would take an infinitely greater interest in industry, and would make it their business to see that it was carried on efficiently, and that there would be secured to the country the establishment of industrial enterprises which would make it absolutely secure against dependence on any foreign country for any essential commodity."

Canada Being Poisoned

In Canada, however, not only have we received no direct help and lead from the Government in connection with planning for our industris after the war in the nation's interests, but a considerable section of our population is keeping the country in a foment of agitation which would tend to destroy rather than to build up. **There is only one way to pay off our accumulated war debts, and that is by producing in field, forest, mine and factory all that we possibly can, and selling these products at as high a margin over the cost of production as we are able to secure.**

As far as export trade is concerned, manufacturers in Canada may be forced in the national interests to sell their wares at a merely nominal margin of profit so as to help preserve the balance of trade and at the same time give employment to the largest possible number of people. The crux of the situation calling forth denunciation of industry, we believe to be just here. Interested parties have poisoned the minds of agriculturists and other classes in this country and have led them to believe that the manufacturers not only received directly an enormous advantage from the tariff which they were not entitled to, and in consequence were making profits which were out of all proportion to the risks involved, but were also actuated by the most selfish motives. It is, therefore, opportune to say fairly, honestly, and emphatically that the average net return from the investment of capital in industry is not more than it should be to encourage men to take the risks incident thereto. Further, while here and there large profits have been made by manufacturers, as is also the case of agriculturists and other classes, yet the history of the past generation shows thousands of abandoned industrial enterprises in which men have lost their all, just as there have been abandoned farms that were not made to pay.

In the United States, according to recent returns made to the Federal Trade Commission, out of 250,000 trading and manufacturing concerns over 100,000 earn no net income whatever; in addition 90,000 of them make less than $5,000 per year, some of whom have very large capital invested. It is the same thing in Canada: the few succeed, whom we all hear about from the housetops, and the many either just get along or languish and die.

Agriculture Needs Home Markets.

The Old-world countries are already taking steps to make themselves more self-contained and self-supporting in the matter of food stuffs. It may not be long, therefore, before the agriculturists of this country realize that they must depend more largely than ever before upon the home markets. To this end, manufacturing industries, if encouraged, should be established all through the West as soon as the population is able to take care of them and raw materials may be secured. No nation can become great that is concerned solely with agriculture. **Every important country in the world, except Great Britain, has found it necessary to adopt a policy which gives protection to its home industries, and many believe that she will be forced to fall into line after he war is over.. Under free trade, agriculture has not prospered.** A writer in **The Athenaeum**, for February, 1918, in a remarkable article, admits that he was "brought up to revere free trade," but believes the time has arrived for fresh consideration and revision. He says: "The politicians must now see that it is life and death for England, and for English men and women; it is no game for political struggles, no academic arena for non-participant, detached philosophers."

This section of my address would not be complete without the statement that the challenge of the grain growers that the challenge of the grain growers, through their official paper, to the manufacturers to declare themselves on the tariff, and to which I was compelled to respond, led me to study the question from their standpoint, as well as ours. If the figures given do not tell all the story, and the agriculturists of the West are not receiving proper consideration, then we should be the first to co-operate with them in trying to remedy their difficulties.

There is said to be a condition existing among the truck farmers and gardeners of the East whereby they receive only an average of thirty-five cents as their portion of every dollar's worth of products sold. If this is correct, it is a wrong that should be righted, and for this purpose the facilities of our Association would be placed at the disposal of those interested.

Concluding Words.

In concluding my address, I desire to thank my fellow officers, the members of the Executive Committee and of the Council, as well as the merbership throughout, for the remarkable sympathy, support and confidence so often expressed during my term of office. This association and experience have been to me a source of happiness and joy that will cheer me throughout the rest of my life. I am sure that I can bespeak the same consideration for my successor.

I should also like to give utterance to my warm feelings of esteem towards our loyal, hard-working, and efficient staff at Head Office and at all the Branches. We have a splendid organization extending from sea to sea, and that is being used to further the interests of trade and commerce throughout our glorious Dominion.

It is a time to build up and not tear down—a time for co-operation and not opposition—a time to stand to our tasks and not be found shirking— a time to act unselfishly and not be moved by greed—a time for national unity and not discord—a time to fight our battles bravely and not lose faith in God that right, not might, will soon rule all the world.—Advt.

POULTRY.

THE CHICK THAT LEAVES A PROFIT IS THE ONE THAT GETS NO CHECK IN GROWTH

Chickens are the quickest meat crop that can be produced. Their production requires no large cash outlay.

Success with poultry depends largely upon how well the chicks are raised. Unless the chicks make a rapid growth during the first few weeks they will not return a profit. Be sure that the chicks come from good stock, provide plenty of house room, and keep them growing all the time. Feed all that they will clean up, but do not waste a bit of feed. Utilize material, whenever possible, but do not feed any musty, moldy, or decayed feed.

The big waste in poultry comes through losses after the chicks are hatched. It is a crime against the nation's meat supply to let a chick die that has eaten feed and used someone's time and energy. Save your chicks by careful feeding, by keeping them in a warm, clean house or brooder, and by protecting them from their enemies.

To be successful with baby chicks you must furnish them:

1. A warm place to sleep—mother hen or a good brooder.
2. Fresh air to breaths—good ventilation.
3. A clean feeding floor—keep floor littered with clean chaff or shavings.
4. Good feed to eat—avoid musty or moldy feed.
5. Feed in small amounts, given frequently.

You must also protect them from:

1. Lice. If hen-hatched, grease the tops of the chicks' heads with vaseline and dust the mother hen.
2. Mites. Spray the house with coal tar disnifectant.
3. Rats. Wage war on rats, put in cement floors and foundation if practical, clean up rubbish piles and other harboring places.
4. Cats. Use covered yards in town while chicks are small.
5. Dirty quarters. Clean houses frequently.
6. Foul yards. Spade frequently or move to new ground.

Feeds for the Chicks

The little chick must not be fed any hard feed until 48 hours after hatching. (However, the mother hen, if one is used, should be fed. Give free access to skimmilk (fresh or soured) or buttermilk as soon as they leave the nest or incubator. When the chicks are 48 hours old feed them in chaff, chopped hay or straw, or shavings.

The best chick feed is pin-head oats, broken rice, and such feeds, if you can secure them, or use a good bran of commercial chick feed. (Feed morning, noon, and night.)

Bread (stale) mixed with sour milk and hard boiled eggs, makes a good first feeding ration, but a change of fine grit must also be given them. As the chicks get a week or two older the boiled eggs may be omitted and a little meat scrap or fish scrap added or the eggs or meat may be omitted entirely if necessary. (Feed midforenoon and mid-afterr oon.)

Dry Mash

If chicks have a good range, dry mash may be left before them all of the time. If confined to a house or small yard then allow them to have dry mash for only an hour or so toward night.

Mixture No. 1:

Rolled oats	1 lb.
Bran	1 lb.
Middlings	1 lb.
Gluten feed	1 lb.

Mixture No. 2:

Gluten feed	1 lb.
Hominy feed	1 lb.
Rolled oats	1 lb.
Barley middlings	½ lb.

For the first three weeks use a mash such as No. 1 or No. 2 or else use a good grade of commercial chick mash.

Animal Feed.

We have raised good chicks on fine cracked corn, clover, and buttermilk, and also on corn, clover, and meat or fish scraps, but more variety in the ration is desirable. The village poultry keeper may be able to furnish his chicks enough animal feed by frequently spading the yard and letting the chicks eat the worms, and by carefully feeding any meat or bones (broken in small pieces) from the table.

It is very important that animal feed form a part of the ration. When chicks have free range they can usually find bugs and insects so that they will make a fair growth, but buttermilk or freshly soured skimmilk may be fed to advantage even when chicks are on free range. Milk is best fed in earthenware fountains. Yarded chicks are frequently stunted because their ration lacks animal feed. If you cannot obtain fresh buttermilk or skimmilk and have more than a dozen chicks you will find that it will pay to secure condensed or dried milk meat scrap, or fish scrap. The buttermilk or fish scrap may be added to the meat dry mash so as to form about 8 to 10 per cent. of the ration. Most of the chick mashes on the market have one of these forms of animal feed.

Green Feed.

The best chicks are grown when green stuff is the most tender. Encourage the chicks to eat large amounts of green stuff by supplying it in abundance. Keep the grass cut short or pastured down close so that it will be tender. If chicks are yarded, carry them all the weeds, waste lettuce leaves, lawn clippings, cut green clover, and other grasses that you have.

Mineral Feeds.

Chicks make very rapid growth and must have plenty of mineral matter in order to make that growth economically. Give free access to fine or chick size lime rock grit, or to finely crushed oyster shells (if you have old hens screen out the fine part for the chicks and give the coarse to the hens.) Chick size dry bone is a very valuable addition when chicks are yarded. Give free access to charcoal at all times.

If chicks have free access to freshly soured skim-milk or buttermilk they do not need water for the first four to six weeks. After that, fresh, clean water should be before the chicks at lll times.

Use all the kitchen and table waste possible. Chicks will relish many things that formerly went into the gar-

CONSTIPATION

CURED BY THE USE OF

MILBURN'S

LAXA-LIVER PILLS.

Constipation is one of the most prevalent troubles the human race is subject to, and is the greatest cause of many of our ailments. If the bowels cease to work properly, all the other organs become deranged.

Milburn's Laxa-Liver Pills work on the bowels gently and naturally. and will cure the worst cases of constipation.

Mrs. Winslow McKay, Jordan Branch, N.S., writes: "I have been sick for a number of years with sick headache and constipation. I tried all kinds of doctor's medicine, but none did me any good until I tried Milburn's Laxa-Liver Pills, and after using four vials I am completely cured. I would heartily recommend them to all sufferers from that disease. I keep them on hand all the time."

Milburn's Laxa-Liver Pills are 25c. a vial. Sold by all druggists and dealers or mailed direct on receipt of price by The T. Milburn Co., Limited, Toronto, Ont.

bage can. Even the experimental war bread will not be entirely wasted if it is fed to a bunch of husky chicks!

J. G. HALPIN.

MARKETING FARM EGGS

It is really an antiquated farmer with ancient ideas, indeed, who fails to appreciate the fact that appearance cuts a mighty big figure nowadays in sales and prices of his products, and where is appearance any more noticeable than in the market egg basket? The question of marketing eggs should be carefully studied by the farmer or farmer's wife, who must needs finally conclude the marketing only absolutely fresh, clean eggs brings most attractive, profitable returns. If your eggs are always of such character they will be known and sought as such, first and at special prices, presumably. It does not require a bit more time to grade and sort eggs for the market immediately after they are gathered, and is really more convenient, since the numbers are not so large to handle.

It must be admitted that the gathering of the eggs has previously been looked upon mainly as a chore of more or less importance, which could be done at any time, generally by the children, and it is a custom still prevalent with some to gather only once weekly, just before needed for market, or upon the huckster's coming, and as a result all kinds of eggs, good and bad, go on the market. Because everyone is insisting upon obtaining the very best of any and every thing for the high prices they are compelled to pay, is just the reason why your returns will fail to be what they should, if you allow dirty eggs, eggs from stolen nests, or that have been under setting hens, or that have been on hand for a long time, or that have been on hand for a long time, to be mixed with your fresh, attractive eggs.

Very small eggs, thin-shelled or dirty eggs, or eggs from stolen nests are best used by the farmer's family. They can thus be utilized in a much fresher condition, at a much less loss. Dirty-shelled eggs are very objectionable, really repulsive; although the egg itself may be large and fresh, it will undoubtedly command lower market prices, being rated as "seconds." And it is really of very little use to wash dirty eggs, as fresh eggs, gathered from clean nests, have a bloom that any amount of washing fails to produce or bring back. Instead of washing away this much-desired lustre, trying to get them marketably clean, look more to the nests, cleaning and freshening them oftener, and gathering the eggs more frequently. Eggs should be gathered once a day, at least, in all seasons; preferably twice during the Summer, when broody or setting hens are so likely to cover them all day long. If you must resort to washing, never use soap, but soak in clean cool water, then remove stains by gently rubbing with clean cloths and perfectly drying them, as packing while they are damp causes molds of different forms. Packing cracked eggs is sure to be a loss, probably before they even reach the home market. A crack ever so small in an egg shell will admit germs which rapidly lessen its keeping qualities. It is said over 13,000,000 dozens of eggs are spoiled annually just by these tiny cracks, which can be avoided by just a bit more care in collecting them. Eggs should always be kept in cool, dry rooms, free from dust and offensive odors.

Now is the time every farmer or farm woman should exercise the greatest care in marketing eggs, not alone for the excellent returns, but because an egg is acknowledged by the best of authorities to be the most valuable food for the human family; hence they should be of first-class quality in these days when the world is facing food famine. Everyone who prepares the market egg basket, egg crates or other container, is an unspectacular patriot, and camouflages along this line are most undesirable.

TAKES 7 POUNDS FEED TO PRODUCE A DOZEN EGGS

With bred-to-lay stock under good management it requires about four and one half pounds of feed to produce one pound of eggs or about seven pounds of feed to produce one dozen eggs. Under conditions where the fowls are supplied with practically every article of food laying hens consume, on the average, about ninety pounds of grain, twenty pounds of green food, two pounds of oyster shells, one pound of grit, and one-tenth pound of charcoal. On the average farm the amount of grain supplied would not amount to ninety pounds because of the considerable quantities of food material secured by the hens while ranging from spring to fall. The farmer should learn to feed well during the winter months because winter egg production is most profitable; on feed cost alone five dozen eggs laid between November 1st and March 1st, would pay for a hen's keep for one year. If the average hen produced an average of twelve eggs each month for the year she would be an efficient hen, making a fair profit over present cost of feed. In proportion to pre-war prices feed prices have advanced more than have egg prices so that the hen must lay about twenty more eggs per year than in 1914. The number of eggs laid above that required to pay for a hen's keep for one year is of greater value now than in 1914 so that the heavy laying hen is more profitable than ever, particularly if the extra eggs are laid during the winter months. Incidentally the poor laying hen was never so expensive to keep. The object lesson to be deduced is that production must be carried on as efficiently as possible, and this means that birds over two years old should very rarely be kept, the majority of the laying stock should be pullets, the layers should be selected with the greatest care, and the method of feeding, breeding and general management should be such as to induce maximum egg production.—M. A. JULL, Macdonald College.

PEERLESS PERFECTION
The Fence For Real Protection
gives life time service. Is made of the best Open Hearth steel fence wire, all impurities burned out, all the strength and toughness left in. Makes the fence elastic and springy. Will not snap or break under sudden shocks or quick atmospheric changes. Galvanized to prevent rust and the coating will not flake, peel or chip off. Can be erected over the most hilly and uneven ground, without buckling, snapping or kinking. Every joint is locked together with the well-known "Peerless Lock." The heavy stay wires we use prevent sagging and require only about half as many posts as other fences.
Send for catalog. It also describes our farm gates, poultry fencing and ornamental fencing. Agents nearly everywhere. Agents wanted in unassigned territory.
THE BANWELL-HOXIE WIRE FENCE CO., Ltd.
Winnipeg, Manitoba Hamilton, Ontario

LOSSES AMONG YOUNG TURKEYS

The principal causes of the high mortality among young poults, as given by Government poultry specialties, are exposure to dampness and cold, improper feeding, close confinement, lice, predatory animals, and inherent weakness due to carelessness in selection of parent stock.

If the coop is built to keep out rain and placed on well-drained ground, the danger from dampness is lessened. During rainy weather the mother hen should be confined to the coop and the young ones allowed to run in and out at will. At such times the coop should be moved to fresh ground each day. If the weather is warm and dry no shelter is required. They will do better in the open. After the poults are three or four days old they may be given free range. Any time cold, damp weather sets in young poults need to be kept in dry quarters.

Great care should be taken in feeding the young poults whenever they are confined. Only when natural feed outside the coop is scarce should they be fed at all. They should be induced to take plenty of exercise to avoid indigestion. Common chick feed, corn bread crumbs, hulled oats and hard boiled eggs, chopped fine, are found to be good in small quantities fed often. Chopped onio ntops, lettuce leaves and alfalfa make excellent green feed to use when green feed cannot be picked up outside. Coarse sand is a good grit.

Lice cause high losses among poults. Those badly infested become weaker and weaker until they die. By dusting the hen when she is set, with some good lice powder, it is a very easy matter to prevent lice from getting a foothold among the poults. A further precaution is to carefully examine the poults every few days. If lice are found about the head, rub on some lard. This kills the lice by closing their breathing pores. If body lice are found the poults should be dusted under the wings and below the vent until the pests are exterminated.

TURKEY POULTS ARE PAYING STOCK

A turkey rearer has the following to say in regard to the success of her work:

"I now have 69 young poults which are doing fine, and have 67 eggs under incubation. I raise my poults chiefly on cottage cheese, corn bread and all the sour milk they will drink. They have farm range, but never go beyond sight. I have a roomy roosting house for them which has a front of wire netting to keep anything from molesting them. On very cool nights the doors are closed.

I keep the house very clean and dry, keeping clean chaff on the floor and when the morning is very cool and damp I do not turn them out but scatter feed in the chaff and they enjoy scratching for it. I think this keeps them contented until it is dry enough to let them out. I never let my poults get wet.

I feed regularly and at the same time every day, five times daily when the poults are less than four weeks' old, four times daily for another two weeks, and then feed three times daily. As they get older, will feed only twice per day. I never feed poults all they will eat up clean, but keep them a little hungry all the time. To prevent bowel trouble and indigestion, I dissolve a half teaspoonful of copperas in two quarts milk or water, and give this twice each week until they are full grown.

Turkeys require quite a litten attention when young, but there is nothing that will pay the farmer's wife or daughter any better for their work.

FOR HOME AND COUNTRY

This Department will be utilized to the best interests of the homes in the Maritime Provinces. Subjects relating to household science and all that stands for better homes and communities will be published on this page. The editor, Mrs. M. A. MacLeod, Sussex, N. B., solicits your assistance in making this page a success and will be glad to publish tested recipes, household discoveries and other articles useful to the homemaker and women's or-ganizations.

HELPING WIN THE WAR

(By May Isabel Fisk)

Oh, no, dear—I can't stop. Don't ask me. I only hopped in for one second as I was passing, to see how you were. I'm nearly dead myself—absolutely worn out; not in spots, you know, but just all over. I stood for two mortal hours yesterday while my new uniform was being fitted—it's the sweetest thing—but it's all for the good of the cause, so I mustn't grumble. I don't know, tho, what Billy's going to say about the trousers: I haven't mentioned that part yet. But it's all frightfully becoming. Mme. Aimee is making a specialty of what she calls "land costumes"—horribly expensive, but then, we must all sacrifice ourselves these days.

Oh, I don't know yet—some kind of digging and then planting things—seeds I suppose. And then pruning them and grafting them. Just what do you do tot make vegetables grow—it's not difficult, I've heard. I shan't do cabbages or turnips or anything that's really not nice. I mean I shall do only the better class of vegetables. I might do something else; I can't tell yet. But, of course, the first thing is to see my costume is right.

I'm determined to help win the war, I told Billy I was going to, he said, "Yes, it's women like you who do 'help win the war!' " I feel sure he meant something horrid. Billy han't always the sweetest of tempers, but whatever I have to suffer—well, you know me well enough, Mabel, to know I'm not the one tot talk about it. I keep things to myself, tho sometimes I nearly strangle, doing it. And untidy! You ought to see Billy's room after he's been dressing—everything all over the place—and always asking me where things are. As I've told him a hundred times, "When I know what I've done with a thing I can always find it, no matter where I've put it."

And as tho we didn't have enough unpleasant conditions to struggle with nowodays, Billy does nothing but talk economy till I'm sick to death of the word—it's the most hateful in the whole language—never means anything agreeable or having a good time—not that I want to enjoy myself, now, of course. I've given all that up forever. I only want to do my duty by my country; but naturally, I want to do it in my own way.

These are perfectly spiffing chocolates. Where did you get them? No, my dear mabel, no more frivolity for me—I'm a changed being since this war. But about Billy. As you know I never talk about my private affairs, but he is being so exasperating just now; you have no idea what I go through. However, I just told him bang out the other night, husbands were no luxury nowadays with all these good-looking soldiers about, and any man could be easily replaced!

He shrieks nothing but, "Save! Save!" from morning till night—and then he doesn't like it when I try it on him. The other day my grocer sold me some splendid tablets—at least, he said they were—called "beefettes," each one equal to a whole roast beef squashed up. Think what you save in the cooking and no mess and no chew to it—and only fiv ecents each. Well, if you could have seen Billy's face when Mary brought in the plattter with just those two tablets with a bit parsley around them. I wouldn't like to tell you what he said—but I shouldn't call it it patriotic!

I've always found this saving business so expensive. Not to speak of the agony of mind—every nerve in my body is worn to a bone—and not a "Thank you" from any one. Of course I started in the kitchen—I cut everything in half except the work. I thought if I gave them twice as much to do, they would be so busy they might not notice how everything else was reduced. I always think things out sort of logically.

That grocer is a perfect genius. He sold me some wonderful stuff to mix with the kitchen tea to make it go further—"dustine," he calls it. A sort of prepared sawdust, I think it is—but most nutritious and helps tremendously. And only a dollar and a half a pound. Such a saving.

I really must be getting on; I haven't a moment to spare. And I want to buy a hat. I want you to go with me; I hate to go alone.

I've got to meet Mrs. St. John later. She's English, you know. You pronounce her name like Injun with an S in front of it. She knows all about how they are running the war in England and she is going to show us how—we've a lot of serious things to discuss. Do you know her? I hardly thought you did; she's awfully exclusive—particular, you know, whom she meets. Now why do you take it like that? I didn't mean anything of the kind; you're awfully touchy. She thinks the world of me.

I want to get up some kind of a fund for something to send the soldiers. Nothing wolly—I want it to be different—so I thought of umbrellas, as I never heard of anyone suggesting them before. But Mrs. St. John wouldn't hear of it—said they never used them. I don't like to think she's just a tiny bit jealous of me. For you know there certainly must be times when it's too wet for them to shoot.

Her sister very nearly married an earl or duke or something, but she's not a bit stuck up over it—Mrs. St. John, I mean. Well, I don't know why she actually didn't, but she certainly very nearly did, because there was some kind of a lawsuit over it. She got quite a lot of money out of it—the sister—not that she wanted it, Mrs. St. John said. Ye—es, an actress, I believe; the stage is thought to be quite respectable in England, Mrs. St. John says. It seems funny, but she says it's so. She' a perfest dear—not much figure—you-never-know-whether-she's-coming-or-going kind. And plenty of hands and feet, but awfully "good form" the other way.

So I've simply racked my brain to think of some new movement that would make the other women wild for not thinking of it first. I'm going to be patriotic if it kills me! And it's got to be something startling and self-sacrificing. You never get your picture in the papers nowadays unless you self-sacrifice a lot.

Now I've noticel this is what you might call a war of substitutes—we are going to eat all kinds of things in place of something else and everybody gives up what he or she was doing to let somebody else go somewhere else. This has taken a lot of thinking out, I can tell you.

Well, now I want to get up a scheme for women like ourselves to take the place of scrub-women who do office floors or something particularly nasty and unpleasant like that, and then release them to learn to be Red Cross Nurses. Isn't it a great idea? Everybody will be talking about it. I've told Mary the days I didn't feel like going I would pay her and she could take my place. Not that I want to get out of it, but that would really be something more of that substituting business—more patriotic, in fact. I just mentioned this to Mrs. St. John—not about Mary, I mean—and she said some one had tried to do something of the kind in England, but the soldiers didn't like it; they said the women had scratchy hands and smelled of beer. But of course they don't do that here—be beery. I think they call them charladies over there.

Of course I'd rather be a nurse myself than anything else. I just adore that uniform and the thing they wear on the head; but then there's Billy again. The firts time I spoke of it he wouldn't hear of it, and when I said I was willing to do anything to help, he just grunted and went on reading the paper. And if you'll believe me, the other day I hinted, mind you, didn't ask, only hinted, something about a new fur coat—I didn't even say it out loud— kind of whispered it—and all Billy said was he'd subscribed all he could to some kind of war something or other and not a penny more for "fallals"—that was the word "fallals"—fancy a fur coat being called such a thing!

And you know just as well as I do, all the new coats are cut differently this year. But do you think Billy cares one bit about that? Well, he doesn't! I can't for the life of me see how he shows his patriotism by letting me go around in a last year's coat. Practically freezing you might say—almost naked. I'm just as much a part of the country as anybody else. Well, never mind—thre are some things I don't talw about. But my ideas are entirely different, tho it is pretty difficult trying to do your duty by your husband and the country at the same time. However, I don't suppose any one ever did their duty because they liked it—this doesn't meany anything about Billy you understand.

Of course, if I did go as a nurse to France I wouldn't do anything unpleasant—not go right into the battles or where there were any bullets, but there must be plenty of nurses needed just to read to those poor darlings when they are tired out or smooth their pillows or something really womanly like that and not disagreeable.

Which reminds, I suppose I've got to spend another afternoon racing around the shops trying to match stockings for my "land" boots—I'm having some brown ones made to order. Not too hideous, you know—rather tricky in fact—I shall dig something, somewhere—I haven't decided. I might go to France after all. Billy might change his mind about letting me go.

Husbands are so different after you marry them! And marriage is so different from what I thought it was going to be. All the things Billy and I were going to do, and we haven't. All the best books we were going to read at night over a roaring fire; all the discussions and talks we were going to have over the big questions of the day! At night he falls asleep over his newspaper and the big questions we discuss are why the bills are so large and if we can't get along with less and economize—that detestable word!

Of course, about going to France as a nurse, there are really several very serious things against it—I don't know what I should do about my hair—I'm a fright if I don't have it waved at least once a week. And how am I going to cheer up sick soldiers if I'm like that? There might not be a thoroughly reliable hairdresser anywhere near the hospital or thing I'd have to go to—pahtisularly if it was anywhere near where they were doing the battles. Dear me, there are so many things to think of when you are as anxious to help as I am. Then I'm looking such a wreck with all this work. I've started a course of face treatments and I must go three times a week; awfully expensive—five dollars a smack, as you might say—I don't want to lose that.

Really, I must go. Put on your things and come with me while I buy a hat. My dear Mabel, surely, you are not getting stouter—perhaps it's only that dress—it gives you a sort of dump. I mean it rather takes away from your slenderness, don't you think? So few women can wear those loose, baggy things successfully. Not that I have ever seen any one look better in those shapeless things than you do. Do you mind my asking how much you paid for it? Not really? You are a wonder! I'm not a bit of use trying to pick up cheap things like that; they don't suit me at all.

Are you ready at last? Here don't forget your bag. I'll take another chocolate before we go. Let's walk.

We'll go in here—those hats in the window aren't half bad.

Oh, just a hat—sort of war hat—one

that will do everything, you know—for morning and afternoon, and, yes, specially for semi-evening wear. And, oh, yes, most particularly for rainy weatheer. And it must be smart—decidedly smart—not too bright, and yet cheerful.

H'm, rather small. Don't you think so, Mabel? You don't? Well, I do. Besides, I don't call mauve, cheerful. Oh, no, I don't want a large hat. Oh, no, those medium sized things have no look at all about them. I don't want anything extreme, mind you—in these days any thing of the sort is inexcusably vulgar—still, not to be one thing or the other, is really nothing at all, is it? Just plain dowdy.

Of course, actually, I don't care at all how I look nowadays; then again, I always think one should do one's best and when you are buying a hat—and only one hat—why, you want it to look like—well, a hat!

That gray's rather nice, isn't it? What do you think, Mabel? Don't you? I do. Wouldn't look bad with my dark blue—still—I don't know—I think it's a trifle old for me. What do you say? Oh, you don't? Well—really—I don't suppose you did "mean anything"—you seldom do. But I know what you said. Never mind.

What about this brown one with the grapes and roses? Nice useful looking hat. But come to think of it, I knew some one once—with grapes, just like this—and she got caught out in the rain, and the grapes all melted and ran down her face in rivers; got all stuck in her hair and she had to have alarge bunch cut off. No, no—not the grapes—bunch of hair.

Besides, they say we shouldn't make any show of food about now—as tho there was much of it—it isn't patriotic—so I don't think I oguht to. I wish I hadn't such a conscience—I'm always doing right and simply hating it. Don't misunderstand me—it isn't the "right" I hate, but the doing it. Now I don't hate Billy's mother, but I hate having her stop wifh us—except when she sits up with the children when they have funny things and I don't know what is the matter with them.

Yes, that is rather nice—but what about that white facing. It will soil so quickly. Oh, you have it without? Yes.—u'mm-m-m! But it is so gloomy looking with that dark underneath—I shouldn't care for it. Do you like it, Mabel? You do? Well, of course my dear, I want you to give your opinion quite frankly, but I didn't think you were going to disagree with everything I ask you.

I saw such a lovely hat the other day. I don't know where it was—but exactly what I want—perhaps you have something like it. It was one of those—well, sort of nondescript shapes with no beginning or end, as you might say, yet perfectly delightful. It had an ornament on one side—or the back, I forget which. No, come to think of it, I believe it was in the front. Anyway it was just in the right spot—one of those lumpy, fascinating things. The material was some shiny stuff. Have you anything like it? You might take a look.

Oh, dear no; that's nothing like it. No, that's worse! Good gracious! And I've just described it! Surely you could tell—I don't believe you listened.

Really Mabel this is a very stupid girl—she hasn't the vaguest idea what I want. And she has such and indifferent look about her.

Now that little black hat over there in the case isn't bad—the one with the cherries—but there, that's food again. No if you put something else on it probably I shouldn't like it. Haven't you got something with those waterproof flowers on it? No I haven't seen them myself but I've heard about them; quite a common thing, I believe. You must have seen them Mabel, haven't you? You haven't? Well, I can't remember where I heard about them, but I do know all the best places keep them.

Oh, no, I don't like that. Mabel, you're looking so tired—I'm sure you

don't go t obed early enough. If you had to rush from morning till night the way I do you would have some excuse——

Heavens, no! Nota hat with all thosethings on it—how would that look in the rain? Yes, I did say I wanted it for afternoon and evening as well, but I want something perfectly suitable for all occasions; you must have something like that if you look hard enough. I thought I explained so carefully what I wanted when I first came in.

Why, how do you do, Mrs. Maitland. Fancy meeting you here. Oh, I don't know, I always thought you made your own hats, somehow. I don't mean they don't look nice, but they have that simple, quiet, home-made touch you can never get in a shop. I think it's so clever of you—and in these times we all want to save. I just dashed in here for about two minutes to pick up something—anything, in fact—and then I have to rush off on my war work. I'm going to meet Mrs. St. John—she's English you know—her sister nearl ymarried an earl or a lord or something.

Oh, yes, thanks, I'm quite well. Billy has a slight snuffle, so of course he thinks he's ill. Men make such a fuss over nothing. He will be quite able to go out by tomorrow—if he wants to. Now when I get a real good, bad cold I'm in bed for a fortnight over it; nobody could budge me. Doctor every day and the whole place upside down; there's no pretending with me.

Oh, yes, I'm quite free as yet. I'm going to do all kinds of war work; I'm willing to do anything—doesn't matter as long as it helps. Why, yes—I'd love to help you. At a canteen? It sounds frightfully exciting; I should love it. I'm crazy over uniforms and I should adore waiting on the men. Oh—oh—did you say help in the kitchen—wash dishes? Oh, yes—yes—certainly—quite right— perfectly true—some one has to do it, and of course I don't care what I do, but—but—now I come to think of it—I shouldn't be able to.

To tell the truth Billy is frightfully pulled down over thi sattack. I didn't want to alarm you by letting you know how badly off he is; it's turned out to bronchitis than a cold. In fact, I'm sure that he will have to go away for a change. When did you say you

FACE COVERED WITH PIMPLES

ASHAMED TO GO OUT.

Many an otherwise beautiful and attractive face is sadly marred by unsightly pimples, blotches, flesh worms and various other blood diseases.

Many a cheek and brow cast in the mould of beauty have been sadly defaced, their attractiveness lost and their possessor rendered unhappy for years.

Get rid of these unsightly and obnoxious skin troubles by using Burdock Blood Bitters.

Mrs. Katherine Henry, Port Sydney, Ont., writes: "Two years ago my face was so covered with pimples I was ashamed to go out. I tried several remedies, but they were of no use. At last a friend advised me to try Burdock Blood Bitters. I got a bottle, and by the time it was used I could see a difference. I then got two more, and when I had used them the pimples were completely gone. I can highly recommend B.B.B."

Price, $1.00 a bottle. Put up by The T. Milburn Co., Limited, Toronto, Ont.

would want tme? How unfortunate! Just the very day we'll be leaving—we were talking about it only this morning. Indeed. I'm just here to buy a simple hat to go away in. Now some other time; you won't forget me, will you? So nice to have seen you. Good-by.

Now what do you think of that for a thoroughly detestable woman. Fancy asking me to help in the kitchen.

Oh, no. I don't like that. I really feel now as tho I shouldn't like anything this morning; that woman upset me entirely. What do you say, Mabel, to having lunch first and then coming back to finish this afternoon? Very well. let's. I'm hungry.

Thanks very much, but I don't care for any of these things you've shown me. Perhaps you could be looking out some others I might like better for when we come back. Good morning.

There. I'll never go in that place again. They don't know how to treat you.

Do you know, I don't think I'll buy a hat after all, but I'll get one of those white fox fur things for my neck and when it rains I'll take a taxi. . And it would be so useful if I go to France!

CONSERVING ESSENTIAL FOODS

Ever since the world began it has been the housekeeper's bit to conserve the family's resources, so making the most of our country's supplies in order to win this war is a task for which she is peculiarly fitted. It may be troublesome at times to change one's methods of cooking, but so long as the war endures there is no doubt that the housekeeper must always be able to substitute one food for another when a shortage in any commodity arises.

For instance, last winter when the sugar supply ran low there were many weeks when it was impossible to purchase enough to even sweeten the breakfast coffee. So we used condensed milk for the morning cup and made our occasional cake or pudding with corn syrup.

When our government asked us to save beef, mutton and pork for the soldiers, meatless and meat extension dishes became matters of public discussion and appeared on the family table with great regularity.

Then animal fat became scarce and even the housekeeper who had been brought up on lard turned to the use of vegetable oils and their compounds, the hydrogenated oils, without complaint.

We learned to combine corn meal and rye with wheat in our bread-making in order to save the sorely needed wheat for the Allies. But now wheat is becoming increasingly scarce so that before the next harvest, when we can secure a new supply, it may become necessary to plan a wholly wheatless diet. Rye, too, is getting harder to buy, and substitute flours with which the Canadian housekeeper has had little or no experience will be the main source of supply.

These we have in great variety. So great indeed that few people realize the bread-making materials that as yet we have scarcely drawn upon. Flours made from barley, corn, oats, rice, potatoes and peanuts are now being produced, and it is quite possible to make excellent breads, pastry and cakes from them either in combination with wheat for yeast breads or alone in quick breads. Used in either way these flours effect a large saving of wheat. A considerable saving can also be made by using barley, corn meal, corn starch or mixed flours for thickening soups and gravies and as dusting flour. Keep a jar or box filled with one of these substitutes near the stove and you will find it wholly unnecessary to use bread flour for this purpose.

There are many nations in the world who get along very well without wheat, and so can we. It is only the knowing how.

Sugar is not so scarce as it was during the winter, but its consumption must be carefully guarded so that there will be sufficient in the country for canning and preserving, both for the home canner and the factories. Our government assures us that there will be plenty of sugar for canning if the housekeeper continues to use corn syrup, molasses, maple syrup or honey in so far as possible for daily consumption. As food conservation is the housekeeper's most important war service, saving sugar for the canning season is a real duty. A great saving in sugar can also be made by canning our fruits instead of preserving them as this takes much less sugar, and waste of sugar from spoilage of jellies can be avoided if the simple alcohol test recommended by the U. S. Department of Agriculture is used to determine how much sugar is necessary with each kind of fruit juice. To do this, place a spoonful of juice in a glass, add to it a spoonful of 95 per cent. grain alcohol, and mix by shaking the glass gently. Pour slowly from the glass, noting how the pectin—the substance in fruit juices which makes them jelly—is precipitated. If the pectin is precipitated as one lump, a cup of sugar may be used for each cup of juice; if in several lumps the proportion of sugar must be reduced to approximately three-fourths the amount of the juice. If the pectin is not in lumps but is merely precipitated, the sugar should be one-half or less of the amount of the juice. If the juice shows no precipitation under this test, it is unsuitable for jelly making and must be combined with apples or other juices rich in pectin.

Before making the test, it would be well to taste the juice, as fruits not as acid as good tart apples probably will not make good jelly unless mixed with other fruits which are acid.

This is a simple precaution, but it will save large quantities of sugar as wel las the disappointment of putting up jellies which won't jelly.

The third war food which we were urged to save was meat. Although meat is not so scarce now as it was during the winter, it is still high in price owing to the grain shortage, and while it is not necessary for us to do without meat because of our patriotism, it is necessary in many families to cut down its consumption because of its prohibitive cost.

A well-selected group of meat economy and meat substitute dishes is well to have at hand.

Fat is the fourth food that war has made scarce, and while the necessity of conserving it is not so imperative as a few months ago, the saving of fat is essential.

Fat has a real relation to the war program, first, as an important energy food for the fighters, and second, in the manufacture of munitions.

As a nation our consumption of fat has been greatly in excess of our needs and as a nation our waste of fat has been enormous. So by using less in the diet and by using more carefully household supplies, our measure of service in food conservation can be easily fulfilled.

There are various methods of conserving fat. First, the economical use of table fats by serving smaller portions and by the elimination of all waste. Second, the saving of cooking fats, and third, the proper use of all types of fat.

A large saving in cooking fats can be made by utilizing all the fats that come into the home. Beef and mutton suet can be rendered, the fats left over after the meal has been cooked can be clarified, that is, freed from all objectionable odors, tastes or color, and all drippings can be utilized for frying and shortening.

The saving of the war foods is not difficult, but it takes most housekeepers into new realms of cookery; and for this reason practical recipes showing how to make the most of these foods have been provided.

Save Fat

To render fat run the lumps through the household meat grinder or chop fine in the chopping bowl. Then heat in the double boiler until completely melted, finally straining through a rather thick cloth or two thicknesses of cheesecloth, wrung out in hot water. By this method there is no danger of scorching. Fats heated at a low temperature also keep better than those melted at higher temperature. After the fat is rendered, it should be slowly reheated to sterilize it and make sure it is free from moisture. The bits of tissue strained out, commonly known as cracklings, may be used for shortening purposes or may be added to cornmeal which is to be used as fried cornmeal mush.

To Render Strong Favored Fats

To mutton, duck or goose fat add equal amount of beef suet or vegetable fat and render same as suet. This may then be used for shortening or pan broiling for meat or fish dishes, and not have the characteristic taste of the stronger fats.

When rendering strong mutton, duck or goose fats if a small whole onion is added the strong flavor of the fat is reduced. Remove the onion before straining. It may be used in cooking.

To Clarify Fats

Melt the fat in an equal volume of water and heat for a short time at a moderate temperature. Stir occasionally. Cool and remove the layer of fat which forms on the top, scraping off any bits of meat or other material which may adhere to the other side.
ingg fg-go- Aro rats cn cf shrdlu etaoi

Fats which have formed on top of soups, of cooked meats (such as pot roast, stews), salt meats (such as corned beef, ham, etc.), or strong fats, such as from boiled mutton, poultry and game, may be clarified in this way and used alone or combined with other animal or vegetable fats in any savory dish.

Care of Fat after being used for Cooking

If fat is used for deep fat frying as croquettes, doughnuts, fritters, etc., while fat is still hot, add a few slices raw potato and allow it to stay in the fat until it is cool. Remove potato, strain fat, allow to harden and it is

I KNOW A WOMAN'S SUFFERINGS

I am a woman.

What I have suffered is a far better guide than any MAN'S experience gained second-hand.

I know your need for sympathy and health.

And the treatment that gave me health and strength, new interest in life, I want to pass on to you, that you, too, may enjoy the priceless boon of health.

Are you unhappy, unfit for your duties? Write and tell me how you feel and I will send you ten days' FREE trial of a home treatment to meet your individual needs, together with references to women in Canada who have passed through your troubles and regained health; or you can secure this FREE treatment for your daughter, sister or mother.

If you suffer from pain in the head, back, or bowels, feeling of weight and dragging down sensations, falling or displacement of internal organs, bladder irritation with frequent urination, obstinate constipation or piles, pain in the sides regularly or irregularly, bloating, dyspepsia, extreme nervousness, depressed spirits, melancholy, desire to cry, fear of something evil about to happen, creeping feeling up the spine, palpitation, hot flashes, weariness, sallow complexion, with dark circles under the eyes, pain in the left breast or a general feeling that life is not worth living, I invite you to send to-day for my complete ten days' treatment entirely free and postpaid, to prove to yourself that these ailments can be easily and surely overcome at your own home, without the expense of hospital treatment, or the dangers of an operation. Women everywhere are escaping the surgeon's knife by knowing of my simple method of home treatment, and when you have been benefited, my sister, I shall only ask you to pass the good word along to some other sufferer. My home treatment is for all,—young or old.

Read My FREE Offer:

To Mothers of Daughters, I will explain a simple home treatment which speedily and effectually dispels green-sickness (chlorosis), irregularities, headaches and lassitude in young women, and restores them to plumpness and health. Tell me if you are worried about your daughter. Remember it costs you nothing to give my method of home treatment a complete ten day trial, and if you wish to continue, it costs only a few cents a week to do so, and it does not interfere with one's daily work. Is health worth asking for? Write for the free treatment suited to your needs, and I will send it in plain wrapper by return mail. Cut out this offer, mark the places that tell your feelings, and return to me. Write and ask for the free treatment to-day, as you may not see this offer again. Address:

MRS. M. SUMMERS, Box 309 Windsor, Ontario

ready for use. The potato absorbs odors from fat.

How to Make Savory Fats

To one pound of unrendered fat (chopped fine) add one slice of onion about one-half inch thick and two inches in diameter, one bay leaf, one teaspoonful salt, and about one-eighth teaspoonful of pepper. Render in a double boiler and strain.

Pastry Made With Dripping

Well made, digestible pastry should nave a minimum of fat to make a crisp, flaky crust. It should be crisp, not brittle; firm, not crumbly. Pastry may be made in large amounts, kept in refrigerator for several days and used as needed. Roll out only enough for one crust at a time, as the less pastry is handled, the better. Whole wheat makes a more tasty crust than bread flour and all rye pastry has even better flavor than wheat flour pastry. Half wheat or rye and the other half cornmeal (white or yellow) makes an excellent pastry for meat or fish pie.

Soap from Leftover Fats

(Fat for soap should be fat which is no longer useful for culinary purposes.)

1 can lye, 6 pounds fat, 1 quart cold water.

To lye ad dwater, using enamel or agate utensil. When cool add the fat, which has been heated until liquid Stir until of consistency of honey (about 20 minutes). Two tablespoonfuls ammonia or 2 tablespoonfuls borax may be added for a whiter soap.

SEPTIC TANK MAKES MODERN CONVENIENCES OF HOME POSSIBLE

Bath, Toilet, and Kitchen Sink may be Enjoyed in Country as well as City

Every home should have an indoor toilet, bath, and kitchen sink. Even though the home be in the country or in a small town, it may, according to Frank P. Goeder, of the Colorado Agricultural College, be equipped with these conveniences. Mr. Goeder says:

"The concrete septic tank solves the problem of disposing of house wastes where the modern city sewer is not to be had. It is intended only as the best substitute for a city sewerage system and when properly built has many advantages over the cesspool. The septic tank will transform the wastes from the house plumbing, and their final disposal will be in a safe and simple way.

"Concrete septic tanks are easy to build and not expensive. The cost of operation and maintenance is very small, and they give satisfactory service indefinitely."

HOT WATER AND EAUTY

One of the quickest, easiest and cheapest ways to gain a lovely complexion is to drink quantities of hot water. And by the way, this is an excccdingly healthy habit. A senator was a nervous and physical wreck some years ago, and attributes his complete cure to a course of exercises an the drinking of quantities of hot water.

As a beginning, drink a glass of hot water on arising, before breakfast of course. If you feel sick at the stomach, this alone will make you better, or the addition of a little lemon juice or a half a teaspoonful of baking soda, will overcome the trouble.

Drink a glass of hot water before lunchcon, before dinner and before going to bed. This flushes out the system, the heat stimulates the blood in the stomach and aids digestion, raises any gas that may have formed, clears out the whole bowel system. If you have pimples, or the blackheads that always accompany this affliction, a few months of this hot water treatment ought to clear up the skin wonderfully.

Few people drink as much water as they should. Doctors say every adult should drink around two quarts daily. This is eight full sized glasses. Four glasses of hot water taken every day would be half as much as you should drink, your tea and coffee and an occasional glass of cool water besides, would bring it up to the prescribed amount. Many thin people have gained flesh by drinking more water with their meals, that is, right around meal times, many fat women reduce by taking water between light meals, when the system seems to want more food. Water overcomes the gnawing feeling, and the body sono accustoms itself to the elssened diet.

Berry Season is here

A Sunbonnet For The Asking

Those who are familiar with the Dr. Chase Plan of Health will not be surprised at our offer. Others may be. Hence a word of explanation is necessary.

Dr. Chase, through a long professional career, firmly maintained that most sicknesses were due to NEGLECT, and held that the neglect was mainly of little things, which added together, make the sum total of human life. At this season of the year, many are called into the fields—especially woman and girls—who are not inured to the burning rays of the sun.

Unaccustomed to the extreme heat, the skin of the face, neck and arms is delicate. The sudden change allows the sun's rays to penetrate to the inner layer of the skin, where the blood vessels are situated. The result—heat, swelling and congestion.

Of course, it is desirable to acquire a healthy tan. Everyone admires it. But no one cares to suffer for days and weeks from sunburn and then have the skin become rough, coarse and hard.

Now, it so happens that Dr. Chase's Ointment not only relieves irritations of the skin, but also keeps the skin soft, smooth and velvety, even under the most trying circumstances.

Again, the results of any irritation of the skin, whether from sunburn chafing or slight scratches and wounds, may prove MORE SERIOUS, since eczema usually has its beginning under such conditions. The success of Dr. Chase's Ointment as a treatment for eczema is too well known to require more than mention here; for it is in the treatment of eczema that Dr. Chase's Ointment has acquired its international reputation.

But about the bonnests. We must not forget them. Why should we spend money in advertising our willingness to give away sun-bonnets? Why should we give them away? That is the pertinent question. The explanation is simple; The Dr. Chase Plan of Health is to prevent illness, as well as to cure it. The sunbonnest cost us less than they would cost you if you had to buy them, and if we can be of service in this little, and perhaps important matter, it will give us pleasure. And, besides, we will have reminded you that the work conducted by Dr. Chase in the days of your grandparents is still being carried on.

While we have provided many thousands of sunbonnets for distribution, it is our natural desire that this offer shall not be abused. DON'T write for a bonnet unless you expect to use it. DO write freely, and without hesitation, if you expect to be exposed to the heat of summer days. The sun-bonnet will be delivered through the mail at our expense.

Along with it, we shall send you—also free—a sample box of Dr. Chase's Ointment. Once you become familiar with the soothing, healing influence of this Ointment, scores of ways will be found in which to use it to the advantage of your skin and of your personal comfort. Edmanson, Bates & Co., Toronto.

Dr. Chase's Kidney-Liver Pills, one pill a dose, 25c. a box, at all dealers or Edmanson, Bates & Co. Ltd., Toronto

WHEN FRYING FISH

Before putting the fish on to fry, sprinkle flour in the hot fat. It will keep the fat from spattering and the fish from sticking to the pan.

SNAPS FOR RIBBON BOWS

Instead of sewing ribbon bows on children's wash dresses, put them on with snap-fasteners. The bows are easily removed when the dress is to be laundered, and can be replaced much more quickly than when sewed in place

STRONGER BUTTONHOLES

A row of machine-stitching around buttonholes in knit underwear prevents them from stretching, and makes them more lasting.

During sickness the telephone-bell may be muffled but not entirely silenced, by folding a slip of paper and placing between the clapper and one bell.

To remove grease stains from carpets, spread a piece of heavy brown paper over the spot and apply a hot iron.

PICKLE AND PRESERVE WHAT YOU CAN'T CAN

Preserves

In preserving, the proportions of fruit to sugar are usually one pound of fruit to three-quarters of a pound of sugar. It is necessary to cook the fruit in the sirup until it is thoroughly saturated.

Peach Preserves

12 pounds of peaches
9 pounds of brown sugar.

Peel peaches. Cut in halves if small, or quarters if large. Place the sugar in an agate kettle, and add enough water to make a thin sirup. Drop the peaches into the sirup slowly. Add the peaches a few at a time. Cook until tender. Pack away in sterilized glass or stone jars.

Pear Preserves

12 pounds of pears
9 pounds of brown sugar
3 sticks of cinnamon.
½ oz. whole cloves

Peel pears and cut into uniform pieces that are not too small. Place the sugar in an agate kettle, and add enough water to make a thin sirup. Add the pears a few at a time, and cinnamon and cloves. Cook until pears are soft. Pack away in sterilized glass or stone jars.

Cherry Preserves

12 pounds of cherries.
9 pounds of brown sugar.

Select firm cherries; remove seeds. Folow the directions given for peach and pear preserves. Pack away in sterilized glass or stone jars.

Strawberry Preserves

12 pounds of strawberries.
9 pounds of brown sugar

Wash berries a few at a time by letting cold water run through them in a colander. Hull; weigh after hulling; place layers of berries and sugar in preserving-kettle. Allow to stand overnight. Remove berries from sirup. Boil sirup until thick. Drop berries in and boil ten minutes, keeping berries under sirup with a wooden spoon. Remove scum that rises. Store in sterilized jars.

Gingered Pears

12 pounds of pears.
9 pounds of sugar.
5 ounces of gingerroot or 2 1/6 level tablespoonfuls of powdered ginger.
Juice and the grated yellow part of the rind of 4 lemons.

Grind pears through a meat-chopper. Put all ingredients in enameled kettle. Cook for one hour, or until amber colored and of the consistency of jam.

Carrot Marmalade

1 doz. grated raw carrots.
3 lemons.
1 teaspoonful cinnamon.
½ teaspoonful cloves.
1 teaspoonful allspice.

Add three-fourths of a cupful of brown sugar to each cupful of grated carrots, and allow the mixture to stand overnight. In the morning, add the strained juice of the lemons, the cinnamon, cloves and allspice. Cook this mixture slowly for one hour.

The cinnamon, cloves and allspice may be omitted and two teaspoonfuls of ground gingerroot substituted.

Grape Fudge

9 pounds grapes
7 pounds brown sugar
½ pound walnut-meats
1 pound raisins.

Wash fruit and remove from stems; remove skins. Boil pulp until skins become loosened, then put the pulp through a colander to remove seeds. Chop skins and raisins; add to sugar and pulp; cook until thick. Add nuts just before it is done. Put in sterilized jars.

Orange Marmalade

Select thin-skinned oranges. Wash, weigh and quarter; slice pulp very thin, remove seeds, and cut rind in thin, short strips. To each pound of fruit add three pints of cold water, cover and let stand twenty-four hours. Uncover; cook for three hours, slowly, until tender. Let stand twenty-four hours, then weigh and to each pound of fruit and juice add one pound of brown sugar. Add rind. Cook slowly one-half to three-quarters of an hour until rind is clear and sirup will jelly; pour into glasses, let cool, and seal.

Crab-Apple Marmalade

Use pulp left over from crab-apple jelly. Rub it through colander; for each cupful of fruit pulp add three-fourths cupful of sugar. Add lemon, cut fine, allowing one-half lemon to every twelve cupfuls of pulp. Cook very slowly, stirring constantly until thick.

Any fruit pulp or combination of fruit pulp may be used. The lemon may be omitted and pineapple substituted.

Plum Conserve

5 lbs. blue plums
3 pounds brown sugar
1½ pounds seeded raisins.
Juice of three oranges
Rind of one orange
Juice of two lemons.

Pit plums, but do not peel. Dissolve sugar in the orange and lemon juice and add fruits and grated orange-rind. Cook until a glaze forms over the surface of the fruits. Put in sterilized jars.

Spiced Currants

Wash, drain, and remove currants from stems. Weigh fruit and use this proportion: three pounds currants to two pounds brown sugar and two-thirds cupful of vinegar. Put all together in preserving-kettle, add ground cloves and cinnamon tied in a bag, one a nad half teaspoonfuls spice to three pounds fruit; cook slowly about one and a half hours.

Pickling

General Directions

1. Always use porcelain kettles and wooden spoons.
2. Green vegetables should be soaked in brine and thoroughly drained to remove the strong flavor.
3. Spice carefully, so that all will blend and not one flavor predominate.
4. Use the best cider vinegar. Do not boil it, for boiling makes it lose its strength.
5. Nasturtium seeds or a small piece of horseradish root placed in each jar keeps the vinegar from molding.
6. For sweet pickles, brown sugar should be used. It makes a richer and better-flavored sirup than white sugar. The sirup should be rich enough to keep without sealing.

Green-Cucumber Pickles.

4 quarts small green cucumbers
2 quarts boiling water
3 tablespoonfuls salt.

Wash and dry the cucumbers, put in stone jar and add brine made with salt and boiling water. Allow to stand for three days. Drain cucumbers, bring brine to boiling-point, pour it over cucumbers, and again allow to stand for three days. Repeat; drain a third time. Scald in the following mixture:

1 gallon vinegar
4 red peppers (chopped)
2 sticks cinnamon
2 tablespoonfuls allspice berries.
2 tablespoonfuls whole cloves
4 cupfuls brown sugar

Pack in stone jar and cover with liquor.

Proportion for Sweet Pickles

7 pounds fruit
10 cupfuls sugar (brown)
2 cupfuls vinegar
1 cupful water
¾ cupful mixed spices
⅛ cupful mace
⅛ cupful whole cloves
½ cupful whole cinnamon.

Watermelon-Rind Sweet Pickle

7 pounds prepared watermelon rind
3 pints vinegar
4 pounds sugar (brown)
¾ ounce cloves (whole)
2 sticks cinnamon
1½ ounces gingerroot.

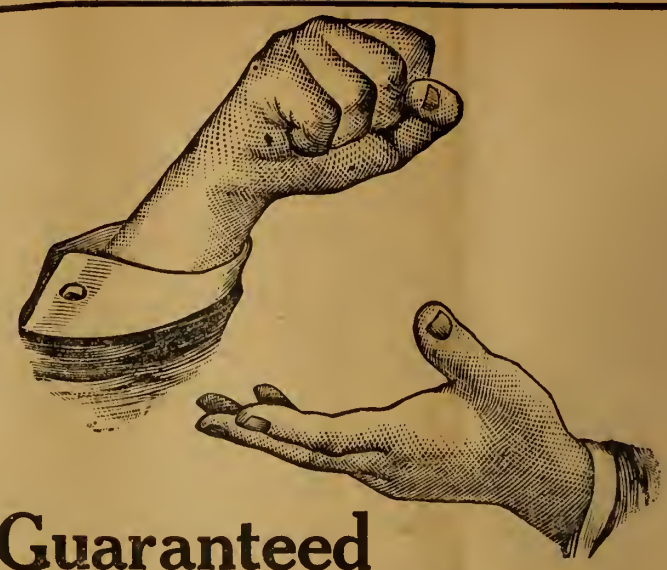
Prepare seven pounds of rind by removing the green part and cutting off the pink melon until the rind is firm. Cut these pieces into uniform strips one inch wide and two inches long. Let stand twenty-four hours in weak brine. (Brine: one tablespoonful salt to one quart water.) Rinse off and scald until tender in alum water. Rinse again in cold water. Place in porcelain-lined kettle; pour in vinegar, sugar, cinnamon, and slightly pounded gingerroot. Tie cloves in bag and add. Cook until rind is tender. Put in jars and seal.

Sweet-Pickled Peaches

4 cupfuls vinegar
5 cupfuls sugar
¼ cupful (scant) mixed whole spices
½ peck peaches

Select ripe but firm peaches. Scald and cold-dip peaches to remove skins, and pare. Make a sirup of sugar, vin-

Clean to handle. Sold by all Druggists, Grocers and General Stores.



Guaranteed
Furnace Results

Heat—sufficient **volume** to **warm** the home,
—even distribution to **all** the rooms in the home,
—the right **quality** to keep the home **healthy,**
—at a **reasonable cost** for fuel,
—with minimum effort in **management,** and
—**without** dust, smoke, ash or gas escaping into the air of the home.

Those are the results you have a right to expect from **your** furnace. Those are what you should **insist** on getting from it.

The Sunshine Furnace, **installed the McClary way,** gives those results.

It has been getting those results in every kind of home and building throughout Canada for eighteen years.

The Sunshine Furnace when installed the McClary way is sold with the absolute guarantee that **you will get those results.**

Engineering Service Free.

McClary's own heating engineers are at your service when you buy a Sunshine Furnace, to give you free expert advice on your home-heating requirements. Write to the nearest McClary Branch, and ask for particulars about this service. A booklet, "Comfort in the Home," makes clear all the things you want to know about furnaces and it is sent free on request.

egar and spices tied in a bag; skim, and boil twenty minutes. Cook peaches a few at a time until tender; put in jar; let stand twenty-four hours. Repeat three times, then pour sirup over peaches; the third time cover the peaches with the sirup which has been cooked down until thick. Pack in sterilized jars.

Sweet Pickled Crab-Apples

2 quarts vinegar
6 pounds brown sugar
2 teaspoonfuls cloves
2 teaspoonfuls whole cinnamon.

Wash crab-apples and remove blossom ends, and add apples. Make sirup of vinegar, sugar and spices, and cook in this sirup twenty minutes; store in jars, boil sirup down, and pour over fruit.

Mustard Pickles

1 gallon cider vinegar
1/3 pound ground mustard.
3 tabelspoonfuls corn-starch
1½ pounds brown sugar
½ oz. turmeric
½ oz. curry-powder
¾ teaspoonful Cayenne
½ oz. celery-seed.

Make a dressing of the above ingredients. One pint small cucumbers; or large ones cut in pieces, may be used. Soak overnight in brine, using one cupful salt to two quarts of water, one pint small white onions, one pint chopped green tomatoes, three bell peppers chopped, leaving out seeds, and one small cauliflower may be used, but should be cooked in boiling salted water until tender. Before adding to the mixture, put vegetables in jar in layers, and pour over them the boiling dressing. Reheat dressing the following day, and thicken if necessary, by making a paste of the cornstarch and a small amount of the vinegar.

Olive-Oil Pickles

8 pounds small cucumbers, sliced
1 pound small white onions, sliced

Let stand in weak brine twenty-four hours (one tablespoonful salt to one quart water). Drain, rinse in cold water, and add:

1 oz. white mustard-seed
1½ ozs. celery-seed
1 cupful olive-oil
½ cupful vinegar
1 teaspoonful salt
1 teaspoonful brown sugar

Mi xwell; put in jars; add vinegar to cover.

CONSERVATION RECIPES

Standard ½-Pint Cup Used.
Measurements Level.

Soft Molasses Cookies

Put in a measuring cup four teaspoonfuls clarified bacon fat (not browned in the least); add three teaspoonfuls boiling water, then fill the cup with N. O. molasses. Add half a teaspoonful salt, half a teaspoonful ginger or spices to taste and one teaspoonful soda sifted with one cup of flour; mix and add enough more flour to make a soft dough. Roll rather thick. Cut in rounds. Bake in a moderate oven.

Maple Sauce for Puddings or Waffles

Cook three-fourths a cup of maple syrup and one teaspoonful of butter till it spins a thread; pour on two egg-whites well beaten. When cool add half a cup of cream whipped very light.

BROWN BREAD

Recipes for brown bread as used by the Domestic Science classes in the Ontario Agricultural Colleges:

Whole Wheat Bread

One cake Fleischmann's yeast, 1 tablespoon melted lard, 1½ cups lukewarm water, 7½ cups whole wheat flour, 1½ cups milk scalded and cooled, 1½ teaspoons salt, 3 tablespoons yellow sugar.

Dissolve yeast and sugar in luke warm liquid. Add lard, then flour and salt gradually, as whole wheat flour absorbs moisture slowly.

Knead thoroughly, being careful to keep the dough soft or "slack." Place in a greased bowl, cover and leave in a warm place, to rise for about hours.

When double in bulk, turn out on a board. Mould into loaves, place in greased pans, cover an set to rise again for about one hour or until light. To glaze, brush top of loaf with milk.

Bake one hour, in a slower oven than for white bread.

(If wanted for over night, use half cake yeast. Water may be substituted for the milk.)

RYEMEAL PANCAKES

2 eggs, well beaten, 1½ cups sour or buttermilk, ½ cup sour cream, ½ teaspoonful salt, white flour for batter, rye meal (sifted), 1 teaspoonful soda.

Into the eggs, milk and cream stir the salt and white flour to make a thin batter; sift the meal and reserve the bran for muffins. Add the soda to a little of the meal and sift into the batter. Add more meal if needed. Bake on a hot griddle.

Rye Bread.

One cake Fleischmann's yeast, 5 cups rye flour, 1 cup milk, scalded and cooled, 1½ cups bread flour, 2 cups lukewarm water, 1 tablespoon salt, 1 tablespoon lard, melted.

Dissolve yeast in lukewarm liquid. Add 2½ cups rye flour, or enough to make a sponge. Beat well, cover and leave in a warm place, free from draft, to rise about two hours. When light, add white flour, lard, remainder of rye flour and salt. Keep the dough rather soft. Kneed until smooth, place in a greased bowl, cover and let rise until double in bulk—about 2 hours. Mould into loaves and let rise until light—about 1 hour. Glaze. Bake slowly one hour or longer, according to size of loaf.

HOW TO USE HOUSE SLOPS

What use can be made of house slops or urine which used to be thrown around an old, large apple tree, which killed the tree? Will you tell me whether this liquid can be utilized as a fertilizer in any way, and if so, the proper mixture. N. B. S.

As a rule these slops are too strong in ammonia for direct application. Diluted half and half with water they can be sprinkled over the lawn with good results. In some cases they are kept in a closed barrel, mixed with water and sprinkled over the grass at night. A better way is to make a compost heap in some secluded place and pour the slops over it. Such a heap may be made of any waste, such as old sods, black soil, weeds or anything that will absorb liquids. The slops are poured on this heap. It absorbs the liquid and holds the plant food. In some cases the pile of coal ashes is used for this purpose and it serves well. The pile is made up with a dishing or saucer-like top and the slops are poured into this depression. The coal ashes absorb the liquid and when needed on the field or garden the ashes are spread like any fertilizer. They carry the ammonia and potash contained in the slops and are not offensive to handle. All liquid manures are richer in nitrogen and potash than in phosphoric acid, and when used on the garden or farm acid phosphate or bone should be used with them.—Rural New Yorker.

RUSTY MOLDBOARDS

For cleaning a rusty plow moldboard a piece of brick is good. Oil should be used on the moldboard when the pow is put away for a few days or longer.

See that none of the "kick" is out of the h p tedder through the loss of a prong from one or more of the forks. Tedding is worth doing well.

Keep the shafts on the horse rake tight. A wide rake seems to put a great deal of side shake on the shafts, and if they are allowed to work loose the ends are liable to split ot.

Wool, unwashed, 71c to 73c lb.

Mill Feeds Very Scarce

The supply of mill feed for 1918-19 will be limited. At present the mills of Canada have no wheat to grind and are consequently engaged in producing substitutes. The shipment of wheat flour to points east of Montreal is forbidden, except under special license from the food controller. The outlook for mill feed is not encouraging. Oil cake is quite scarce. The Maritime Farmer has booked some at $64.00 per ton F. O. B. Montreal, for September delivery. Arrangements are also being made to get a supply of special feeds. The analysis of this is now being made and a number of cars will be brought into the provinces to try out. If they prove satisfactory, a large quantity will be bought.

HERE'S A CHANCE FOR FEED

The Maritime Farmer has a chance to get a supply of special feed, which will be handled at cost for Agricultural Societies, the members of which are subscribers for this paper. The outlook for feed this fall is decidedly bad. Southern Alberta's wheat crop is a failure. The amount of wheat which will be alloted Canadian mills to grind this season will be much less than a year ago. We can supply a feed which shows the following content: protein, 13 per cent; fat, 4 per cent; fibre, 19 per cent; carbo hydrates, 64 per cent. This will be available at $25.00 per ton, and freight charges, which, under the new freight tariff will be advanced 25 per cent. If you want this feed, act quickly. Send us your order and accompany it with a notification from your bank that the draft for the feed will be met on presentation. There is no other agreement we will consider. The Maritime Farmer handles this business at absolute mill prices. We get no commission whatever on the goods. You pay your own bills, but we will not order any goods until we have a bank guarantee as to payment. Please remember this and save time and expense.

Demand For Eggs Steady—Potatoes Tending Lower

Notwithstanding the inferior quality of eggs now being offered in the country owing to the extreme heat that has prevailed of late there has been no easing off in prices in the interior owing to the fact that the demand for supplies continues good. In sympathy with the above and the liberal movement for the season of the year for immediate consumption the tone of the local market remains firm and a good steady business is passing in a wholesale jobbing way. The receipts today were 1,562 cases, as against 1,274 for the same day last week, and 996 for the corresponding date a year ago.

We quote wholesale prices as follows:

Selected new laid eggs....51c to 52c
No. 1 stock.....47c to 48c
No. 2 stock.....45c to 46c

An easier feeling prevailed in the market for potatoes today owing to the larger offerings of supplies on the public city markets, and the prospects are that prices are still lower in the near future. The demand today was fair for small lots to meet immediate wants, and sales were made at $2.25 to $2.40 per bag of 80 lbs., ex-store.

The trade in maple product was slow, and there were no new features in the market to note. Prices rule firm on account of the small supplies available. Maple syrup, in wood, was quoted at $1.90 to $2 per gallon, and in tins at $2.10 to $2.25 of one gallon. Maple sugar continues to be enquired for at 23c per lb.

Millfeed and Rolled Oats

Montreal—There was no further change in the condition of the market for millfeed today, but the feeling in all lines was very firm at the recent advance in prices noted on account of the continued steady demand for supplies and the somewhat limited offerings. Sales of feed cornmeal were made at $68 per ton, including bags.

delivered, put oat moullie at $67, pure barley feed at $67, mixed moullie at $55, shorts at $40, and bran at $35. A good steady trade continues to be done in rolled oats for both local and country account, and the tone of the market is firm, with sales of broken lots of standard grades at $5.20 to $5.30 per bag of 90 lbs., delivered. A fair volume of business was reported in cornmeal and prices were unchanged, with sales of broken lots of Golden grade at $6.25 to $6.40, and bolted at $4.50 to $4.75 per bag.

Cattle Trade Dull and Hogs 25c Higher at Toronto

Toronto—At the Union Stockyards the receipts today consisted of 461 cattle, 141 calves, 411 hogs and 159 sheep and lambs. The cattle trade was decidedly dull and slow. Light, thin cattle, particularly heifers, are in very poor demand. Several cars of western cattle of this class just arrived, found a very slow market and prices very shaky. It was difficult, in fact to get bids on light medium butchers steers and heifers. Weighty steers are all right and in good demand for export. Three or four small lots of good heavy steers sold around $14 to $14.50. A few fat cows and bulls sold at about steady prices up to $10.50. For the rest, little was offering, and less was wanted. Sheep were steady, and lambs a little firmer. a few extra choice selling up to $20. Choice veal calves held steady, but common sort were weak. Hogs were firm and 25c higher at $19.25, fed and watered. A few were sold at $19, but most at the 25c higher.

Dairy Produce Trade

Montreal, Aug. 2—The receipts of butter today were 415 packages, as against 1,033 for the same day last week, and 755 for the corresponding date a year ago. At Gould's Cold Storage today the offerings amounted to 700 packages of creamery butter, for which the demand was fair, and all sold at 42c to 42½c per lb., f.o.b., country points, which prices are about ½c per lb. lower than this day week. There was no actual change in the condition of the local market, but the undertone was easy owing to the fact that the demand was somewhat limited from both local and outside buyers, and business on the whole was quiet.

We quote wholesale prices as follows:

Finest creamery.....43¾c to 44c
Fine creamery.....43¼c to 43½c
Finest dairy.....38½c to 39½c
Fine dairy.....37c to 37½c

The receipts of cheese today were 18,239 boxes, as compared with 35,582 for the same day last week, and 23,818 for the corresponding date a year ago. At Gould's Cold Storage today there were 6,000 boxes offered, for which the demand was good, and all sold at 22¼c per lb., f.o.b., country points. Owing to the increase in railway freight rates which went into effect on and after August 1st, exporters of cheese in some cases stated today that they would, no doubt, have to reduce present prices now being paid to factorymen in order to meet the same.

The Dairy Produce Commission is paying the following prices:

No. 1 cheese.....23c
No. 2 cheese.....22½c
No. 3 cheese.....22c

Grain Prices Score an Advance

Winnipeg, Aug. 1.—There was little or no change at today's session in the cash markets, except that there was a better inquiry for oats. The offerings today were very light in all grains. Oats closed 1⅜c higher for July, October ¾c higher and December ¾c higher. Flax closed 4½c higher for July and 1c lower for October

Fluctuations in grain today were:

Oats:

	Open.	High.	Low.	Close.
July	87¼	.89⅜	.87⅛	.89⅜
Oct.	81½	.82⅜	.81	.82⅜
Dec.	77⅜	.78¼	.77⅜	.78¼

Flax:

July	$4.52	$4.58	$4.52	$4.58
Oct.	4.46	4.48	4.46	4.48

The Baled Hay Market

According to advices from Ontario the yield of hay in the province on the whole this year will be little, if any, below an average yield per acre, and the acreage is large. With reference to the province of Quebec, the yield in many sections will be much larger than last year and the quality much better. There was no change in the condition of the market today, business being still rather quiet and prices unchanged, with car lots of No. 2 hay quoted at $14, No. 3 hay at $13, clover mixed hay at $8 to $10, and inferior grades at $4 to $6 per ton ex track.

LIVE STOCK AND THE ORCHARD

(Continued from page 683)

industries of the American farmer I refer to poultry raising. Poultry should not only be part of the general plan on the fruit farm, but in addition should be kept on every American farm. It is rather unfortunate that we find grain farmers as well as fruit growers going to the butcher or the groceryman for poultry that ought to be produced at home. Poultry on the fruit farm will not only furnish the family with food stuffs among the most nutritious of all that are available for human consumption, but in addition, if properly handled, can be made to yield during the year no inconsiderable income.

The great fruit industry of the Northwest will lose nothing of its importance as a highly-organized specialty, but on the other hand will be strengthened and rendered more stable and permanent by the adoption of diversification to the extent of live-stock keeping along the lines suggested above.—By Prof. L. J. Iddings, University of Idaho.

TIRES ADVANCE IN PRICE

The Maritime Farmer has been advised that the cost of automobile tires, which it has been supplying to its subscribers, advanced to-day seven and one half per cent. Please govern yourself according when ordering. We still have a few 30x3½ in tires on hand, which will be sold at the old price, to subscribers only.

MAKING A DRY CONCRETE FLOOR FOR THE PIG PEN

Some hog breeders say they prefer not to have concrete floors in farrowing pens because they are colder than wood or dirt floors and are often damp. I have met other breeders who say they would not have any other than concrete floors. These are personal opinions gained from experience, and usually the men who like the dirt floor have a gravelly subsoil or their house is placed where it has the advantage of good natural drainage. A concrete floor will not shut out water or dampness unless it has good underdrainage.

Personally, I prefer the concrete floor because it can be kept more sanitary. If sufficient litter is kept in the pens the floor can be made dry and warm, and this is essential at farrowing time. We put a concrete floor in the hog house that has given good service, and does not collect moisture on the surface.

The foundation of this floor is cinders which were secured from a local heating plant and electric light plant. They form air spaces beneath the concrete so that in wet weather little moisture is present where the concrete joins them. They were put in about six months before the concrete so that they would become well settled; a depth of from four to six inches is sufficient, or even less than that may be used.

In laying the concrete the cinders were first thoroughly wetted and tamped to within five inches of the height of the desired floor. Then four inches of concrete, mixed in the proportion of 1.6, was put on and well tamped to make a good union with the cinders. This was mixed with water so it would pour but not thin enough to run. The top one-inch layer was mixed in the proportion of 1.5, made thin enough to run, and when smoothed and troweled a film of water would form on the surface.

The same method was followed in cementing the eight-foot driveway and feeding floor. In the driveway we started at one end and made blocks about three and four feet wide. This is a convenient width to work handily. If the blocks are made wider than this it is more difficult to level them and do the troweling work.

Stakes were driven on each side of the driveway and a straight edged board nailed in position lightly to them, then another stake was driven in the centre to prevent the board bulging. As soon as a block or section was filled and leveled the nails were pulled from the stakes and the stakes and board were moved on to make the next section. There is no need of waiting till the concrete gets dry, but care must be exercised when removing the board to not pry it up and break the edges.

In a long narrow space like a driveway it would be a little handier I expect to put a form down the centre lengthwise and complete one-half of it at a time. If the other half can be finished a few days later it makes a convenient place to handle and mix the convrete on the part that has hardened.

J. L. JUSTICE.

WHEN COW CHOKES HOW TO TREAT HER

Editor "Maritime Farmer"

Kindly advise re the following questions and oblige:

1. What is the best thing to do when a cow is choking?

2. Have you any remedy to offer as to making a cow milk easier?

OLD SUBSCRIBER.

Ans.

1. The first thing to do is to examine the mouth and throat and see if you can locate the cause of the trouble; also examine along the left side of the neck to try and find out where the obstacle is lodged. If you can see or reach it, put a plow clevis crosswise in the cow's mouth, run your hand down the gullet and bring it up. In order to grasp it easily let someone hold it firmly on the outside. If you cannot reach it, pour half a pint of raw linseed oil down as a drench, then move the obstruction by working it with the hand from the outside. If no linseed oil is at hand use other oil. If this fails use a probang. There is a small wooden gag that goes with this instrument. Have a man stand on each side and hold a horn and one end of the gag, keeping the cow's head in line with the body; oil the probang and pass it through the hole in the gag, and on down until it reaches the obstacle; then carefully press on it until the obstruction is forced into the stomach.

If you cannot press the cause of the trouble down and the animal becomes badly bloated, tap her on the left side to let the gas out. A trachar and canula is best for this purpose, but in case of emergency a pocket knife may be used.

At the first appearance of choking and before an animal becomes bloated a gag, made of a round piece of wood about two inches in diameter should be run crosswise of her mouth and held there by a rope passing over her head and fastened to each end of the stick. This may be left in position for some time; it will usually prevent bloating and if the obstruction be a piece of turnip, mangle, apple, or potato it will usually soften and pass down into the stomach without any further treatment. However the oil

the paint-protected, weather-proof farm

The finest farm buildings soon get to look "dingy" if they are not kept painted.

Worse still, the omission of the Spring painting leaves them open to weather-attack and time's decay.

And—with materials so high as to make every building worth double today what it was worth in 1913—you are making a mistake if you let a building "go to seed."

Have your farm a "model" farm—have it fresh with paint—have it protected with a paint that affords real protection—

B-H "ENGLISH" PAINT 70% Pure White Lead (Brandram's Genuine B.B.) 30% Pure White Zinc 100% Pure Paint

If this paint were sold at a price half as high again as any other (which it isn't) it would still be the economical paint to use on your house. In sheer covering capacity it has no equal. A gallon of it goes so far that you'll buy less *of* it and yet do more *with* it. Paint with B-H "ENGLISH" PAINT this Spring—and your house is protected for years, where a coat of ordinary paint will last but a few months.

The difference lies in the above formula basis. What other paint is so correct in this respect that its makers guarantee it? What paint can a dealer furnish you that has anything like the quantity of white lead in it that has B-H "English".

This was the formula when lead was lower in price—this is the formula still; even though lead is extremely high in price. It HAS to be the B-H formula; because the guarantee that calls for it, is printed right on the B-H cans. We could not cheapen B-H "English" Paint even if we wanted to. So it's your safe paint as to quality, your sure paint as to covering capacity, your dependable paint as to durability. Find the B-H dealer in your town. He's the man to buy from.

Other B-H Products of Sterling Worth

For Interior Finishing

The name "China-Lac" suggests a china-like finish—and that is just the kind of finish you get from the use of China-Lac—the perfect varnish stain. Being transparent, it preserves the "grain-beauty" of the natural wood—at the same time giving splendid color effects. Easy to apply—not affected by either hot or cold water.

For Staining the Roof

Our "Anchor" Brand Shingle Stains are especially prepared to preserve wood from decay. Easy to apply—on rough surfaces they give a better effect than paint. Shingles may be dipped or brushed on. Come in 19 different colors.

For Plaster Ceilings and Walls

Use Fresconette—a flat tone oil paint. Fresconette comes in a variety of shades. It is absolutely sanitary, for it may be cleaned with a damp cloth or thoroughly washed at will.

For Varnishing a Floor

Our "FLOORLUSTRE" finishes a floor with a lustrous coating of the most durable enamel. Will stand hardest wear — will not show scratches. Excellent for interior floors. For Porch Floors, Ceilings, Posts, etc., where surface is exposed to the weather, use B-H Porch Floor Paints.

Imperial Barn Paint affords a convenient protection for barn and outbuildings, made of good material, covers well, dries hard, goes farthest and lasts longest.

BRANDRAM-HENDERSON LIMITED

MONTREAL HALIFAX ST JOHN TORONTO WINNIPEG CALGARY EDMONTON VANCOUVER

and manipulation on the outside of the neck will help the situation.

All stockmen should own and keep in a convenient place for cases of emergency like this, a trochar and canula and a probang. Two or three dollars will purchase the outfit and the expense is insignificant as compared with taking chances on losing an animal.

2. We know of no successful remedy for this trouble. In very bad cases a bistoury or small bladed knife may be used to cut the sphineter muscles that surround the opening and which holds the milk; but this invariably causes splattering and disagreeable milking and is most likely also to cause leaking of milk. Some have claimed that the teat-plug is a successful remedy, but these are apt to break the muscles and cause the same difficulty as cutting, and unless very carefully used it is likely to introduce germs and cause garget. You might try some veterinary supply house for an expansion implement which was advertised some years ago for this purpose, but which has not come into general use.

The best course is to beef a hard milker and turn her off. She should not be kept and used as a breeder as she is likely to transmit this defect to her offspring, even to son's daughters.

MEND THE GRAIN BAGS

It is quite a while yet until threshing time, but the time will roll around and catch you without your grain bags mended. Look them over now for you have more time now than you will have when the whistle blows next threshing time. Bring them in and go after them some stormy days. Take one of the poorer bags for patches. Lay a bag out flat on the floor or table and fit a patch to the hole. The patch should be about 2 inches larger than the hole and the corners should be slightly rounded. Lay another bag on top of this one and fit a patch to it, and so on until patches have been fitted on all of the bags needing them.

Mix up a smooth thick paste of flour and cold water. The paste must not be cooked. Take one of the bags to be patched and lay it on a smooth surface and with a paint brush paste the patch well. Also paste around the hole where it will be covered by the patch. Place the patch in position and touch lightly with a hot iron until the paste on the patch begins to cook, then rub down thoroughly. The hot iron cooks the paste and unites the patch and bag almost as one piece. By rounding the corners of the patch, they are not as liable to peel.

On a large hole it is best to place a piece of paper in the bag under the hole so the patch will not cook to the oppcsite side of the bag. It is not necessary to trim the holes, merely smooth out the ragged edges and they will be cooked to the patch evenly. I have bags patched in this manner that have stood for years. It is quicker, easier and just as good as the old methods and much cleaner, for where is there a farmer's wife who likes to take a bundle of dirty rags on her sewing machine or in her lap to patch? There is only one precaution needed. Bags patched in this way should not be allowed to become thoroughly soaked with rain for this may cause the patches to peel and loosen. I. H. W.

UNDERGROUND GROWTH OF PERENNIAL WEEDS MUST BE KILLED

Perennial weeds are the most difficult ones to hold in check or eradicate, according to Prof. W. W. Robbins, of the Colorado Agricultural College. Prof. Robbins says: "They live over and propagate themselves by means of underground growth. These underground parts grow readily, even though cut up into a number of pieces. In them is stored an abundance of reserve food, which is called upon to build new top growth. This food is made up in the leaves. Consequently, if the top growth is persistently kept down, the underground parts will at length be depleted of their reserve food, and starve. Practically all schemes of eradicating perennial weeds have one object in view and that is the starving of the underground growth. This object may be realized by fallowing, by the use of cultivated crops, by the use of smother crops, or by a combination of these."

UTILIZING INNER TUBES

The rubber from inner tubes can often be used to advantage about the farm. After a tube has passed its service on the car the rubber is still lively and if kept in a dark place where the air is not dry it will maintain its lively character for quite a long while.

If a piece is cut off the tube about one-half inch wide it makes an excellent band for putting around good tubes that are kept in the car, holding them in a convenient bundle. Two of these are needed for each tube.

The same kind of a band is also useful for putting round jars of fruit that are stored in cupboard shelves. The band of rubber keeps the glass sides from knocking together, preventing breakage of the jars.

The bands are also useful in holding documents, letters, etc. A bunch of the bands kept about the house may come useful in many ways.

If the tube is split lengthwise and narrow strips cut from it, the strips can be tacked about door and window casings to keep out the cold air in winter. A flat piece makes a good matting on the door step. In a thirty-four inch tube there are about eight square feet of rubber, so that a single tube will provide quite a great deal of rubber for many uses, and this rubber may come in handy in many ways about teh shop and house.

It is surprising that farmers will continue to plow and work around a stone or stump in the middle of a field, when it is so easy to remove such obstructions. Several instances of this kind have been noted only recently. A stick or two of dynamite properly placed would get ride of them in short order and the expense would be insignificant. Any hindrance to cultivation is expensive and at this time is decidedly unpatriotic.

Hippopotamus meat is said to be as good as pork, but the chances are that a lot of hippopotamus running about would muss up a back yard almost as much as chickens.—Marion (Ohio) Star.

What Will You Do For Help?

FARM help is scarce, but this condition can be relieved to a marked degree by using machines that accomplish more work in a given time with less man power.

Why should the farmer cling to horses—a slow, expensive means of power—when every other business is adopting the truck and thereby reducing the cost of hauling, speeding up deliveries, and saving for human needs the food that the horses would otherwise consume?

The motor driven truck can work constantly at maximum load under the burning summer sun, or in the coldest weather. Unlike the horse it needs no rests while working, it eats only while in actual use, and when the day's work is done it requires very little attention, and leaves you free for other "Chores" about the place. Then, it can be housed in one-quarter the space of the horses, wagon and harness it replaces.

It is a mistaken idea that a truck is useful only for driving upon paved roads. The Ford can be driven all over the farm, and used for hauling grain, potatoes, fruit, roots, fertilizer, wood, stock, milk or any other product. The speed it travels, the time it saves, and its low upkeep cost appeal very strongly to all users of the Ford Truck. If you need help, order your Ford One Ton Truck today.

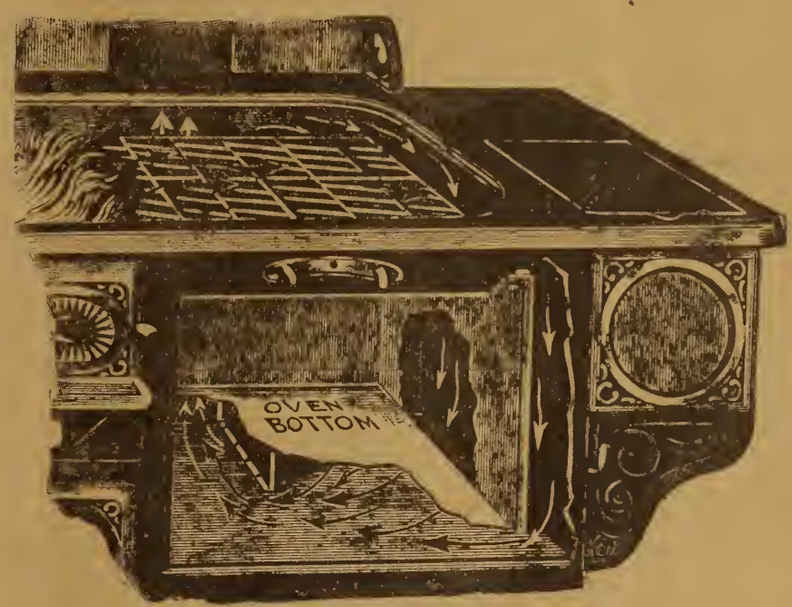
An Envelope of Heat

THE Kootenay oven is practically surrounded with heat—even, unvarying and steady.

Over the top of the oven and down the right hand side, the heat passes in a steady current, then underneath the oven till it strikes a guiding bar that sends it to the front, then straight across to the back.



The oven itself is constructed of heavily nickelled steel which absorbs and distributes the heat evenly and quickly to the interior.

Thus the oven is practically surrounded with an envelope of heat on five sides—left, top, right, bottom and back, and the outside is protected by a heavy steel door with air-tight joints so that not a particle of heat can escape.

The outside envelope of the heat flues, or the body of the range, is insulated with asbestos and protected with air-tight joints.

"Service in the Kitchen"—Booklet Free

This is only one of the many features of the Kootenay Range described in a beautiful little booklet, "Service in the Kitchen," which will be mailed free on request. It tells all a woman wants to know about a range before she buys it.

RENEWING THE STRAWBERRY BED

One question frequently asked is: "How lon may a bed of strawberries be profitably kept?" This question is incapable of a eneral answer. There are a number of factors which affect the answer, such as stand, freedom from disease, presence or absence of weeds or grass, variety and the relation of the bed to the rest of the farm operations. Commercial rowers usually fruit a bed for oneor two seasons and then plough it up, because usually by this time the grass and weeds have gotten such a hod that it is easier to plant a new bed than to clean up the old one. When the weeds are kept out, the fertility kept up and diseases do not appear a bed may be kept for several years, especially for home use. The size of the berries even under the most favorable conditions, will diminis after the second year. With varieties like Dunlap, Warfield and Bederwood, which produce lare crops of medium sized fruit, a bed would become commercially unprofitable sooner than other varieties which are not so inclined to overbear. Plants grown under hill culture aer frequently grown more than two years and those varieties adapted to hill culture are the ones which, under the matted row system, will prove best adapted to a longer fruiting period than two years.

In case it is decided to leave a bed for another season, it should be mowed after fruiting and the leaves either burned or raked off. Burning is risky and should be undertaken only when there is plenty of moisture in the ground and just enough mulch left to enable the fire to run. When this is done, a brisk wind will speed the fire quickly across the field without allowin git to linger long enough tocause injury. In case the leaves are not burned they should be raked off, together with the surplus mulch. After burning and raking, the middles are then plowed and worked down, the weeds and grass removed from the rows, fertilizer applied between the rows and the bed iven the same treatmnt as a newly set bed.

NEW CUCUMBER DISEASE

It is sometimes a matter of comment that we have so many more diseases and illnesses than we had a few years ago—as though the medical profession, instead of combating disease, was putting in its time searching through the human body for new illnesses and frailties.

But it is not among humans alone that science has been rooting up new diseases. Within recent years attention has been called to new potato diseases, and along come the scientific sharks and tell us of "Cucumber Mosaic," a disease somewhat similar to the potato mosaic, of which considerable has been heard during the past year.

A report from Ottawa Experimental Farm says that this disease of cucumbers is not well known in Ontario, but has of late been appearing more frequently. It is found that there are three types of the cucumber mosaic, one of which is very damaging. This is the White Pickle Mosaic, which greatly dwarfs the plants and causes the fruit to grow in a lumpy misshapen condition. The distortion in the fruit is due to irregular growth. Certain areas become sickly, assume a light yellow or nearly white color, and grow very poorly. The remainder of the surface is normal, retains its dark green color and grows much faster, thus producing distorted leaves or lumpy fruit.

In the other two types the leaves are the parts most affected. In one of these types the leaves are mottled with light, yellow green areas, and the plant is weakened and dwarfed, thus reducing the yield. The Mottled Leaf Mosaic is not so damaging as the White Pickle type. The third type is known as the Speckled Leaf Mosaic, and while the leaves become spotted with sickly areas, as the name indicates, this form of the disease is not considered to be very damaging.

Like other Mosaic diseases, these cucumber troubles are transmissible from one plant to another, though they are aparpently not due to any fungus or bacterial parasite. If the juice of a diseased plant be injected into a healthy plant, the disease will be produced and in the field transfer of this kind is thought to be brought about by means of sucking insects.

It has been found that the common wild cucumber also suffers from this trouble, and that insects will carry it from these wild plants to the cultivated crop in spring. It is not thought to be carried to any considerable extent in the seed.

In view of the transmissible nature of the disease, it is advisable to destroy and to burn up the dead vines in the fall.

GRADING AND PACKING VEGETABLES

No one can tell a rower whether a given practice will be profitable for him or not. However, one idea that is commonly held is usually wrong, that is, that it does not pay to grade and pack carefully when vegetables are cheap. In times of over-supply, it becomes a question whether produce can be moved at all or not. The grower with attractive goods is able to make sales when the neighbor leaves his crop in the field. It is true that it costs money to putproduce up in good shape, but this difficulty has been met by many growers by studying their operations with the idea of achieving greater efficiency. Many workers are exceptionally slow in bunching, tying, sorting and the like. Such workers should be taught to make better speed or should be put at some other task for which they are better adapted. Young people with nimble fingers can frequently be used to good advantage in this work. There are cases on record where tomatoes have been graded and packed in a packing shed at a lower cost than others would expend for packing directly into market baskets. In these operations piece work offrs a splendid incentive.

Perhaps it will be advisable for you to build a concrete celar for storage. The methods for this are quite simple, and products are accessible at all times. Be sure to make ample provision for ventilation at both top and bottom; otherwise you cannot secure circulation of air.

When putting up portiers or window shades do not nail them to the woodwork of the arch or window. The government needs all the metal it can get and nails should be conserved.

VALUE OF GOOD ROADS

They Constitute the Initial Step Towards Industrial Prosperity

By the roads of a country shall a country be known. The leading nations, at almost any period of the world's history, have been great road makers. It would indeed be ardous to find a subject more interesting, more timely or vital to Canada's interests than the subject of good roads. We all live on roads of some description and are living in a civilized influence. The better the system of roads in a country the higher the degree that influence manifests itself on the people. Were there no roads we would be back in the dark ages, when people lived in high distrust of one another.

Each country has its own particular road question to solve, but the country that grudges money for its roads, in the years to come, will find itself called upon to pay very heavily for its parsimony. When peace is declared there will be some millions of men with a fair understanding of the importance of good roads. The knowledge is being acquired through the progress of the war, where the roads are the great arteries along which the armies move, where breakdowns and obstructions mean shortage of food, shells, and support, while good roads with transports well organized enable hard-pressed armies to fall back with small loss, or a victorious army to press on with advantage. It was the good roads of France that was the chief medium in saving Paris in 1914, by the rapid transport of the armies by means of motor cars and trucks along the roads to the threatened sectors, and, again, the Germans' threat against Verdun was frustrated when the French organized a service of 4,000 motor vehicles, operating in both directions, night and day, without intermission, along a well-construeted loop line railway between both extended flanks of their army.

The men who have experience, each in his own way according to his need, the utility of the high-class roadway in war, are the men who will emphasize the importance of the roads in the life of a nation, and insist that the problem is one of national as against localized importance.

No Industrial Progress Where Mud Roads Prevail

Tbe same conditions that give facilities to the war worker will become necessary to the industrial worker in the peace time conflict on which future progress of Canada will depend. All industries of city and county progress in proportion to the case with which communication, exchange and transport of products are made. The making of a roadway that is fit for heavy motor traffic need not be resented b yany other industry on the ground that it is for the selfish interest of the motorist. The road will prove a boon to all industries for progress in every national and individual enterprise is bound up in the road question.

The value of any farm depends upon the distance it is from a town. In a large measure the distance to town depends upon the condition of the roads. It costs some farmers as much to get their farm products to town as it does to raise their crops. Few farmers figure on their expense, and wonder why they annually have not a better balance. Good roads make for speed and conservation, while bad roads are followed with isolation and decay.

You do not find a community of prosperous people with fine farms, good fences, up-to-date buildings, fine herds of cattle, teams and turnouts that are the pride of their owner, and withal surroundings that suggest refinements, culture and contentment, along a highway where the roads for many months of the year are impassable because of mud, ruts, and holes, that impede the progress and dampen the ardor of the traveller. No, these anomalies are not co-existent. The neglect of its roads has often enough been a mark of a nation's decay, and in this respect the parts of peace have proved more destructive than the ravages of war, for peace has destroyed what war has built.

Half Made Roads Bad Economy

In constructing new roads it is not necessary that all should be main roads. But what is necessary, however, is that all roads should be solidly built and surfaced to withstand the wear and tear of modern traffic, for poorly built roads are a source of expense to the community charged with their upkeep. This method of economy is expensive and falls heavily on the industries of a community, reacting on the prcie of all commodities that have to find their way over them to market.

Road interests are not inevitably opposed to railway and other transport interests. There is ample need for both, for, indeed, the transport of some classes of goods calls for road transport just in the same degree that carriage of other goods logically demands railway facilities. The railway, particularly in sparsely populated districts, may act as the main artery for goods and passenger transport—while the roads act as tributary feeders.

It is clear to every one, even those who have only a superficial knowledge of modern business conditions, and the elementary laws of economics, that any country possessed of good transport conditions can more readily attract capital for development than a country not so circumstanced. The many men now fighting in the war, will, on their return, have a broad outlook in regard to the value of roads, and these, using their influence, will be able to point out the obvious advantages of spending generously in the first place in order that suitable arteries of traffic may be constructed, and guard against the folly of building unsuitable roads that add so much to the retail cost of all transported goods, and are also more costly to maintain even in unsatisfactory condition.

It is turning the wheels back many years to introduce a discussion as to whether good roads are worth while. Without going into details the easiest way to answer this question, is to state that every civilized nation has sooner or later found that a system of permanent roads was absolutely essential to its proper development.

There is no country in Europe which has not an adequate system of national highways reinforced by a system of local highways in the smallets units of government.

Road Problem in its Right Perspective

In the near future the road problem as it is now known in Canada will be non-existent for the simple reason that new constructions, and even repairs to the highways will be carried out with a view to suiting the particular traffic they will be called on to carry. It is being freely stated that the road of teh future is to be a motor road pure and simple, but that opinion is going too far. There is no reasonable doubt about the utility of the motor driven vehicle and it is not now seriously disputed, that, for whatever purpose the roads may be used in the future they will, in any case, be suited to carrying the fast-moving, heavy-loaded vehicles.

Whatever the reason, whether pressure for good roads is brought to bear by farmers. cyclists, motorists or commercial interests. the fact ermains that the importance of suitable roads is now receiving recognition, and, although many questions of detail have still to be settled, most authorities, local and national, in practically every country, are beginning to view the road problem in its right perspective. Nine miles out of ten in Canada are just plain mud roads, earth roads, and clay roads. These are the roads that farmers depend upon to haul their products to the market and supplies to their farms. Nine farms out of ten are olcated on mud roads and it is no wonder that boys and girls leave home. Nine-tenths of the energy and

(Continued on page 736)

A MATTER OF DOLLARS AND CENTS

What It Costs With Horse and Wagon to Haul on Different Kinds of Roads

Tight surfaces laid on well-drained sites with good grades are the twin essentials of good roads. Proper planning is necessary to secure both. The comparative costs of hauling by horses and wagons over different road surfacings has been worked out carefully and in an article by Joseph H. Pratt, in the "Annals of the American Academy," 1910, is worth giving here.

Pro Rata Cost of Hauling One Ton a Distance of One Mile On Level Roads:

	Cents	
On asphalt	2.70	
Dry stone paving	5.33	(double)
Mud-covered stone paving	21.30	(8-fold)
Broken stone road in good order	8.00	(3-fold)
Good dry sand-clay road	8.00	(3-fold)
Broken stone with ruts and mud	26.00	(10-fold)
Earth—dry and hard	18.00	
Earth—with ruts and mud	39.00	
Loose gravel	(5) 51.60	
Dry sand	64.00	

On Level Grade, as a Standard, a Horse Pulls 1,000 pounds On a Rise of:

1 ft. in 100 (1%)	900 lbs.
1 ft, in 50 (2%)	810 lbs.
1 ft. in 25 (4%)	540 lbs.
1 ft. in 10 (10%)	250 lbs.

Important Meeting of United Farmers

Want a Farmer to Represent Carleton County--Appreciate Farm Help Leaves---Against Tax Exempt Victory Bonds

Woodstock, Aug. 22.—Over a hundred farmers met this afternoon in convention to hear the report of the local political leaders in reference to the election by acclamation of a candidate of the United Farmers' Association of New Brunswick to fill the vacancy now existing in Carleton County. The committe reported A. D. McCain as willing to agree to an independent candidate although he felt that he was not in a position to speak for the Liberal party. F. Smith and W. S. Sutton would be guided by the action of a Conservative convention. Some discussion took place over the advisability of placing a candidate in the field and it was the opinion of several speakers that it would be too soon for the organization to enter the political arena. One speaker said, "If we are beaten it wil ltake years to get over it." The matter was finally dealt with as in the resolution. The membership was stated to be 1,500 with stock sold to the amount of $6,000 for the co-operative branch of the association.

William Reid in the course of his speech said that many of those exempted for farm duties were not on farms. He knew of young men in Centreville exempted who are not farmers, who are roaming around the country. Strong exception was taken to the government putting a price on hay and compelling the farmer to sell to produce dealers. Mordon Sharp complained that every move for consideration made by the farmers was construed as unpatriotic.

Exception was also taken to the action of the military authorities in keeping returned men for home service. The best home service they could render would be on the farms.

Resolutions Passed

The following resolutions were passed:

We, the United Farmers of New Brunswick, wish to express our satisfaction with the present progress of the war in France, and feeling that the production of food is one of the most essential things in the prosecution of this war, and wish to put ourselves on record as being willing to do our utmost in the way of greater production ,and wish to express our appreciation of the leave granted to our soldiers in training in Canada, to assist in gathering the harvest, as without this help it would have been impossible to get the harvest before a good part of it would have been wasted; and we also wish to express our appreciation of the fact that the government has decided thatthere shall be no harvest excursions from the Maritime provinces to western Canada as weconsider thatall the available help will be needed in the maritime provinces the present season.

Whereas, it is reported the people of Canada will very soon be called upon toloan our government $12,000,000 more to carry on the war to the end of the year,

And, whereas this immense sum, added to our former public debts and probable future war loans as well, will saddle our patriotic people for many decades tocome with almost unbearable taxes, however equitable such taxes may be levied on our several industries an dour different classes of people,

And whereas, the greater part of the loan must necessarily come from our wealthy people and our millionaires, because farmers and laborerers have little or no ready cash for investment.

Therefore, resolved that this association of farmers unanimously protest against the exemption from taxes of any more war bonds that may be issued now or later on because such exemption from domestic taxation will result in largely relieving the most of our wealthiest people from their just share of making good the fearful cost of winning the war, while on the other hand such exemption of these vast sums of money, belonging to the rich must necessarily double the burdens which the farmers ad laborers must carry, driving more and more people off the land and further increasing the cost of living for the masses of the people.

We, the United Farmers of New Brunswick in convention assembled, feel that in the past the farmers of the province have not been consulted as they shuold be in regard to the carryrying on of the dept. of agriculture and whereas, we, the United Farmers more fully represent the agricultural interests than any other organization.

Therefore, be it resolved that in the future the United Farmers of New Brunswick should be consulted in matters affecting the farmers' interests.

Whereas in the past the government has obliged the farmer in disposing of his hay to pass it through the hands of produce dealers and consequently having to pay a large commission. Therefore, we put ourselves on record as being oposed to this procedure, and ask the government to buy direct from the farmers of the United Farmers' Co-operative Co. of New Brunswick.

That we memoralize the government that they shall not set a price on hay or any other farm product that would be below the cost of production, or below what the local market would afford us.

Moved by Joseph Palmer that we take a standing vote of this convention as to whether or not we will stand by a man brought out by the farmers. Passed unanimously.

We, the United Farmers of New Brunswick, wish to express our appreciation of the vote of the convention pledging ourselves to stand together for our own interests in the politics of the country, and feeling dissatisfied with the old political parties with regards to their attitude toward United Farmers of New Brunswick by electing by aclamation to fill the vacancy for Carleton county in the local assembly, but in view of the fact that this convention is not representative of the branches of Carleton county, we recommend that this matter be laid over for future consideration.

Interpretation and Limitation of Tuberculin Test

Prof. H. G. Hastings, Wisconsin College of Agriculture

An inquiry was recently received from one interested in the raising of dairy cattle, asking for the latest ideas as to the interpretation of the temperatures taken in making a tuberculin tests. The reply could only state that there are no "latest ideas" in regard to this point. The stockmen have been led to believe that the tuberculin test is a procedure which, when carried out by careful and experienced men, will detect all cases of tuberculosis in the herd and will not point a finger at any non-tubercular animal. In other words, by its aid at one stroke the diseased animals can be detected. Their removal from the herd, followed by the disinfection of the stable, should result in a tuberculosis-free herd. At least this has been the belief of many stockmen, a belief due to the statements that have been made by writers whose words carried conviction. Sometimes the effort to eradicate the disease from a herd in the manner indicated was successful and the results were according to the theoretical view. More frequently the results were not so successful and it required not one test, but many before the disease was overcome. Until very recently a large part of the practicing veterinarians have also held a similar view. They considered the test to have no limitations. Indeed, the writer has heard veterinarians state that they would guarantee to free a herd from the disease by one or two tests.

It is easy to create a wrong impression in the minds of the people and a most difficult task to overcome such an impression. It has long seemed to the writer that a recognition of what the tuberculin test can do and what it cannot do is something about which the cattle raiser should be well informed, for otherwise he will lose faith in the test and abandon it. It is certain that but rarely can a herd be freed from tuberculosis with one or two tests. It is likewise certain that it is the only agent by which the disease can be eliminated. If consistently and persistently used it will furnish a high degree of protection to the farmer.

Tht tissues of a tubercular animal are sensitive to the products formed by the tubercule bacillus. These products are contained in the tuberculin. When the tuberculin is injected beneath the skin, a fever results in the case of a tubercular animal; when the tuberculni is dropped into the eye of a diseased animal, inflammation follows; and if injected into the skin, a swelling is produced in the case of a tubercular animal. The tissues of a healthy cow are not sensitive to the products of the organism and so no effect follows their introduction. Nature does not provide uniformity in form or function. When a series of tubercular animals are injected with tuberculin subcutaneously, in most of them a marked fever results; in others the fever is so slight that one cannot be certain whether it is actually the result of the tuberculin or a normal fluctuation of temperature. In other words, the temperature increase in a diseased animal, due to tuberculin, may range from 0° to 5° or 6°. Somewhere an arbitrary line must be drawn. The animals on one side must be classed as reactors, those on the other side as non-reactors, or better, three groups of animals will result; those concerning which there is no question as to their having given a positive reaction, those which are classed as having given a negative reaction and a questionable group.

In a recent book on bovine tuberculosis, Dr. DeVine of New York, gives the following interesting results of a study of the temperature records and the post-mortem examination of 2,000 tubercular animals:

Comparative Percentages of Different Temperature Readings

Temperature Degrees	Generalized Tuberculosis	Localized Tuberculosis
102-103	1	1
103-104	5	6
104-105	19	21
105-106	75	72

It is frequently the practice not to class a reaction as positive unless the temperature reaches 104°. If that rule had been strictly applied in this case, from 6 to 7 per cent. of the diseased animals would have been left in the herd. Too high a temperature standard will leave some tubercular animals in the herd; too low a standard will result in the removal of healthy animals. The owner must decide which he considers the lesser of the two evils.

It is true that in certain stages of the disease the tendency to give a marked reaction is less than during other stages. As for example, during the incubation stage a reaction does not occur, nor does it occur during the dormant stage which is so frequently met in cattle. Taking in all sources of error, it does not seem possible to detect over 85 per cent. of the diseased animals at any one test. If for, example, we have 100 diseased cattle in a herd of 300, and a test enables us to remove 85 of them, we now have 200 healthy cattle and 15 tubercular animals in the herd. A second test detects 12 of the 15, a third test 2 of the 3, so now our herd consists of 200 healthy animals and one tubercular. This is an illustration of what is likely to happen if the disease does not spread between the tests. If an open case is left in the herd, the disease of course will spread. The idea the writer wishes to convey is that by the persistent use of the test, tuberculosis can be so reduced in a herd that it will cause little loss and usually absolute eliminations can be affected. The test will likewise protect the herd from the introduction of the disease in animals purchased, not absolutely, but very effectively.

8here is a tendency to class any deviation from what normally occurs in a tubercular animal as a questionable reaction and the owner is advised to keep th eanimal for a retest. For example, the fever may be more prolonged than is usually the case. Such a test was recently brought to the writer's attention. The fever due to the tuberculin appeared at about the normal time but instead of the temperature falling within three or four hours, it remained high until the twenty-secand hour after the injection. This led the veterinarian to recommend that the animal be kept for a retest. The owner had had no reacting animals in the herd for five years and considered it wise to take no chances. The animal was removed and slaughtered. The examination revealed tubercules of large size in the lungs and adjacent glands. If the animal had been left in the herd she might not have reacted to the retest and before another annual test was made the disease might have spread to other members of the herd.

The points that need to be emphasized are: first, that the tuberculin test has many limitations that must be taken into account in its practical application; second, that it is the only agent by which we can hope to combat the spread of this disease.

ANTHRAX

By Chas. H. Higgins, Pathologist, Ottawa

Anthrax is a highly infectious disease of animals that is contracted by the introduction of infected matter beneath the skin (blood or tissue from an animal dead of the disease, earth or any other material containing living anthrax organisms). So serious is the infection considered that it is mentioned as one of the scheduled diseases under "The Animals Contagious Diseases Act." It may affect all warm-blooded animals, and men frequently contract anthrax and die as a result of the infection.

Anthrax is most frequently seen in cattle, sheep, horses and hogs. It may occur at any season of the year, but especially in the summer or fall. Outbreaks are often associated with tanneries. Tanneries may have hides in process of manufacture from animals dead of the disease, and the anthrax organisms being removed in the "soak" water in turn infect the river or creek into which the "soak" water is discharged, as well as any low lying land which such water may overflow.

Cause

The anthrax organism was one of the first to receive attention, owing to the fact that its relatively large size permitted it to be seen in the blood with the microscopes used in the early sixties of the last century. Before this, while the disease was diagnosed, the germ causing it could not be identified, as the available microscopes did not magnify sufficiently. We owe Pasteur, the French chemist, whose researches on various phases of fermentation paved the way for a fuller understanding of diseases and their causes, a lasting debt of gratitude for giving us much information which today is common knowledge regarding anthrax.

Anthrax is caused by a rod-shaped bacillus, organism or germ, which multiplies with great rapidity in the blood. It has the power when drying of transorming itself into a resting stage or "spore" and this "spore" is capable of withstanding high temperatures and other untoward conditions which would destroy the life of the anthrax germ if it were not in the spore form. It is this resting or spore stage that makes it so difficult to effectively deal with an outbreak. Stables, yards and even the soil become impregnated with the virus or germ and their effective disinfection proves a somewhat difficult matter. In dealing with an outbreak the Department takes into consideration the various factors involved, treating each in such a manner as to safeguard the interests of all concerned.

Diagnosis

The diagnosis of anthrax is not a difficult matter to one trained in bacteriological science, as an examination of the blood of a dead animal almost instantly reveals the cause. To the lay person the sudden onset of the disease and the rapid cause, followed by death should arouse suspicion. When suspicious, the fear of anthrax should be communicated to the nearest veterinary inspector, whose training will permit him to accurately judge the nature of the malady from which the beast died. He will also determine the steps that must be taken to prevent its further spread. When anthrax is suspected, the skinning of the carcass must not be undertaken, as such a procedure liberates the germs which would otherwise be almost completely destroyed by its decomposition. Such carcases should be burned immediately, but when this is impossible, deep burial in quicklime must be practised.

Occurrence.

Outbreaks of anthrax have occurred in various parts of Canada, probably the most serious being the one at Swift Current, Sask., in 1901, when the sheep of the Canada Land and Ranch Company were very seriously affected. tA this time some thirty thousand sheep were exposed, of which three thousand died. Three human beings were affected, but fortunately as a result of prompt treatment recovered. Three horses died of the disease, but no cattle were affected. An area approximately seventy-five by twenty-five miles in this district along Swift Current Creek was infected. The outbreak was brought under control as a result of the sanitary precautions inaugurated by Dr. J. C. Hargrave, of Medicine Hat, and the writer. Vaccine was used as an additional precaution on a large number of the sheep. oN record of a recurrence has been repor ed in this locality since that time.

The diagnosis was confirmed by laboratory methods and animal inoculations. The source of the infection was not definitely established in this instance, but circumstancial evidence indicated that it was brought by sheep shearers direct from the Argentine Republic in South America.

In the fall of 1916 an outbreak occurred at Oshawa, Ontaria, where some twenty-five head of cattle and one horse died of the disease. The history here indicated that isolated deaths had been caused by the disease in previous years btu were incorrectly diagnosed, and at no time was anthrax suspected. A number of men contracted the disease and in March, 1917, one death in man was recorded, this being the first human case in this locality where the diagnosis was confirmed by microscopic examination. The banks of the creek into which the wash and other waste water from a tanenry were discharged were found to be nifected with anthrax.

Smal loutbreaks are frequently reported and are promptly dealt with by this Branch each year. It has been the policy for many years to recommend the vaccination of animals on infected premises. When this procedure has been effectively carried out untoward results from anthrax infection are rarely experienced.

Anthrax Vaccine

As we recommend the use of anthrax vaccine where anthrax has occurred, a short description will doubtless prove interesting.

Anthrax vaccines are attenuated or weakened cultures of the germ, causing anthrax (bacillus anthracis). The process of attenuating or reducing the strength of the germ is confined to the laboratory and cannot with safety be conducted elsewhere.

Anthrax vaccines properly used, afford protection, resistance or immunity to a subsequent artificial or natural anthrax infection.

To protect or immunize an animal against anthrax, two vaccines are required and protection or immunity is the result of the animal passing through two mild, properly graded attacks of the disease, which, as a rule, cause no inconvenience to the patient save a slight elevation in temperature. During these two mild attacks of the disease it is advisable to take particular care of the animals, avoiding exposure to inclement weather and extremes of heat or cold.

Vaccine used on an animal already affected with anthrax will not protect such an animal, nor will it prevent its death. The use of anthrax vaccine, during or immediately after the occurrence of an outbreak of anthrax, may be followed by death in some instances due to the stimulation of the anthrax germs already in the system of the animal. Such accidents cannot be prevented. In the use of anthrax vaccine the temperature of the animal to be vaccinated should be taken immediately before inoculating, and, in the event of the temperature being elevated, vaccination should be deferred until the temperature of the animal is again normal.

It is possible to establish immunity or resistance to anthrax very rapidly and also to remove some of the dangers attending vaccination through the use of a serum-vaccine. The serum-vaccine treatment of animals consists in the injection of a protective serum on one side of the neck of the animal to be treated, and immediately thereafter inject the vaccine on the other side of the neck. This establishes an effective protection or immunity in about ten days, overcomes the second handling of the animals to be protected, and the vaccine itself is safer to use. The protective serum if used during an outbreak on animals actually diseased, or such as have a high temperature, will assist them in overcoming the infection and may prevent deaths from anthrax.

In cases of human anthrax, experience has shown that this serum gives the greatest hope of success when used as soon as the infection is suspected. A number of recoveries have been attributed to the use of this serum.

All animals that are to be quartered on premises known to be infected with anthrax should be vaccinated at least once a year, otherwise there is danger of their contracting this disease.

The Hay Shortage

In some sections of the Maritime Provinces a sohrtage ofhay is reported. In consequence there will probably be a demand for hay this season. In order to supply members of agricultura societies at cost, the Maritime Farmer is endeavoring to arrange for the shipment of hay direct from the producer to the buyer. This will enable the farmer to get every cent possible out of his hay and will also assure the buyer of the closest possible price. The prices for hay should be fixed very shortly. If you require hay in your agricultural society, please advise the Maritime Farmer. We will arrange for shipments to you at the closest price available. We expect to give particulars of the Maritiem Province hay market in each issue of the Maritime Farmer. Watch our market page for prices.

Fall Pasture for Sheep and Swine

Sheep weaning time is one of the most critical periods in the development of the lambs. If well fed during this time they will not only mature earlier but will develop into larger animals. A convenient arrangement is to have a small enclosure of one or two acres, preferably near the farm buildings, for the lambs. The field may be sown to a cultivated grass, such as brome or western rye and the aftermath from the hay crop used for the pasture. In this case it will be necessary to have the hay taken off comparatively early in the season so that the aftermath will make good pasture. If, in addition, the lambs have access to a small lot of unharvested ripe oats they will make good progress.

If it can be arranged, a plot of rape will be found most useful in furnishing a large amount of succulent feed. The rape may either be pastured off or may be cut each day and fed the lambs. Both methods were tested out at the Scott Station last season. A plot of the Dwarf Essex rape in the dry season of 1917 gave in one cutting 7 tons 1,840 pounds per acre of green feed.

Swine.—For fall pigs, half-grown pigs and brood sows, some fall pasture is necessary for economical feeding. The rape will give an abundance of feed during the early autumn months. In light soils brome grass will help out later in the season, and early sown fall rye will provide pasture late in the autumn. The three kinds of crop might be in the one small field. A small patch of ripe oats and peas will give the young pigs a good start off for the cold weather. For this use, the oats should be of a short-strawed variety and ample seed should be used to secure a thick stand. The time for sowing the grain will depend on when the pasture is required; usually it can be sown late in May or early June to good advantage.—M. J. Tinline, Acting Superintendent, Experimental Station, Scott, Sask.

Ground Oil Cake Available

There is a quantity of ground oil cake (old process) which is avaibale at $59.00 per ton f. o. b. New York. An export license for this has been arranged for by the Live Stock Branch of the Department of Agriculture, Ottawa. The oil cake tests 34 per cent. protein. It is an excellent buy at the price and the Maritime Farmer will be pleased to handle orders for agricultural societies who wish a supply. There is also a quantity of ground linseed oil cake, about 3,000 tons, stored in Montreal, which is being offered at $62.00 per ton f. o. b. Montreal. The Maritime Farmer will place any order for this feed which may be forwarded. Act quickly if you want some. The feed situation is far from satisfactory and mill feeds will be very scarce this year.

Facts About Sheep

The world's sheep stock has decreased by 54,000,000 head since the war began.

The sheep supply of the United States has decreased by 3.000,000 head in the last five years.

Canada's sheep population has dwindled by over 200,000 head since 1914.

Australia's sheep supply has dwindled by several million head on account of drought.

Breeding ewes are not going to go lower; they are very liable to o higher in the next few months.

The exports of mutton from Canada during August, 1917, increased by nearly 50,000 pounds over the corresponding month last year.

The exports of meat from the United States for the year ended June 30. 1916, amounted to 1,339,193,000 pounds compared with a three-year ante bellum average of 493,848,000 pounds.

These exports went chiefly to the Allies, whose capital stock of animals has decreased by 33,000,000 head since the war started.

THE MARITIME FARMER.

And Co-operative Dairyman

Registered Trade Mark

Semi-Monthly Journal devoted to the interests of the farmers of the Maritime Provinces.

Official Organ of The Farmers and Dairymen's Association of New Brunswick; The Nova Scotia Farmer's Association; The Nova Scotia and P. E. I. Fruit Growers' Associations; The New Brunswick Fruit Growers' Association; The Maritime Stock Breeders' Association; The Maritime Bee-Keepers' Association; The New Brunswick Poultry Association, and the Newfoundland Agricultural Board.

Subscription price $1.00 per year. This paper is sent to subscribers unless a definate order for discontinuance is given.

The date after your name on the little green label on front page, is in every case the time to which your subscription is paid.

OUR GUARANTEE.—With each subscriber to the MARITIME FARMER, we positively guarantee, while his subscription lasts, that no advertisement is allowed in our columns unless we believe that any subscriber can safely do business with the advertiser, and we agree to make good a ny loss which any such subscriber may sustain hy trusting any such advertiser who may prove to be a deliberate swindler; but we do not undertake to adjust trifling differences between subscribers and responsibl advertisers. To take advantage of this guarantee, written come plaint must be made to the publish er within one week from the date of any unsatisfactory transact ion, with proof of the swindle and loss, and within one month from the date when the advertisement appeared, and the subscriber must prove that in writing to the advertiser he said :—"I saw" your adv. in the MARITIME FARMER.

THE RURAL ROAD CAN MAKE OR MAR A COMMUNITY

Unquestionably the railroad is necessary for long hauls of heavy and bulky commodities, such as coal, grain, lumber and similar materials, but the short haul or small shipments of odd products, for speed, for direct deliveries, good roads will give the motor truck a big advantage.

Good roads are the people's railroads. On them they may travel with their own conveyances at their own choice of speed, stopping where desired and at an expense to meet their purpose. Good roads meet their purpose. Good roads accommodate themselves to the tourist, the transient, the large shipper and the small. On the good road there is no restriction, no embargo or as little of the road as suits his purpose. As far as the road lies in his direction he follows it, and only regrets when he must leave it.

While we need both good roads and railroads, while each has its place in our economic life, there are recent developments which seem to favor the immediate construction of one or the other as well the intensive use of those already in use. Railroads are private, or at the most, semi-public enterprises, and they depend almost entirely on private capital for their construction, and on revenue for services performed for the money to operate. Good roads are always entirely a public affair and, with few exceptions, are free to all for travel and service except each must furnish his own means of locomotion and power, and they must be maintained by some form of general public taxation or special assessment.

Railroads, being under one general head, must move systematically and on a definite schedule. Good roads, on the other hand, permit an almost unlimited traffic, each unit travelling at its own speed, stopping when desired, and independent of the rest of the vehicles on the highway. Railroads require terminals, switch yards, sidetracks, etc. Good roads can deliver their goods anywhere in the cities through which they pass or with which they connect. The terminals, as such, is almost unnecessary, as shipments by trucks are usually delivered direct to the consignee. Granted that large concerns already have rail facilities in their plants or yards, there is usually some delay in placing cars where they may be unloaded direct into the warehouse or factory. A rail transfer requires the united efforts of several trainmen, engineer, fireman, conductor, brakeman and the office force of agent despatcher, etc. Good roads operation requires a truck driver with no need of special instruction except as to destination.

Operation of the railroad requires a force of train despatchers, operators, switchmen, etc., beside the numerous other officials. Road traffic requires none of this as in only our largest cities does the traffic become heavy enough to require more than a "traffic cop" at the busy intersections. Confusion of orders on a railroad usually results in a train wreck and a blocking of traffic and travel for hours or perhaps days. A breakdown of a truck results in only one truck being delayed until it can be repaired or its load transferred to another. Railroads require an expensive right of way, which must often be purchased at great cost, and maintained. Good roads follow the established roads, and can be adapted to local conitions. Railroads must be built at a very low grade, while good roads can be built on relatively steep grades, or reloaded as desired. Traffic on a railroad is seriously interfered with when changes are being made, while with good roads a detour may add a little to the time required but will not otherwise greatly dealy or inconvenience the traffic.

New centres of population will require railroads as well as good roads. New factories and industrial plants will require sidetracks and switches. Communities will require terminal facilities. Every railroad built will mean miles of good roads leading to it, and every mile of railroad or good road will mean further development of the district through which it passes. It will mean higher prices to those who sell, yet lower prices to those who buy, through bringing producer and consumer nearer together. It will mean marketing the produce which now goes to waste, and giving full employment to those who are idle part of the time.

MEN MUST BE BRED FIRST

Two distinct lines of breeding and fitting are required for every successful stock farm—with a third one as subsidiary. In the first place a man must be born and developed into such perfection as to work harmoniously with nature and perfect the skill which wil produce the perfect animal. Secondly, the animal must be bred with careful consideration of his ancestry, and blood lines combined to bring together the ancestry of a splendid line of forbears, and perfect the past work in the newest creation. Then, finally, subsidiary to this is the necessity for developing the best possibilities of the farm on which the animals are reared.

In the first place, we have our definite standards for men. No amount of feeding and fitting in a physical sense will make an oustanding man—and the question of heredity probably plays a smaller part in the result than is the case with cattle. The fitting in the case of a breeder lies in his education and experience—a fitting of the brain, and while it is a common saying, and a very true one, that a successful stock man is born and not made, it is equally true that any man, regardless of heredity, will be useless as a stock breeder without a course of training.

The education of a stock breeder is a comprehensive one. It starts with the public school education, and branches out at once into the rudiments of cleaning the stable and feeding the stock. Later it embraces a study of the conformation of the animals, and finally a close study of pedigrees and blood lines—the keystone of all of which is a keen eye for the fine points of an animal.

Having the trained man, the next consideration is the breeding of the stock itself. The breeder must start with the best material at hand, and from that point moves on into a new world of experiment and surprise. He sees in his mind's eye the ideal for which he is working, and he sees in his own herd the failures to come up to this ideal. Therefore, with a carefully balanced study of pedigree and type he brings new blood into his herd, and carefully notes the result in the offspring. There is no rule by which the results may be forecasted. The vast mystery of breeding lies in the impossibility of knowing what the result will be—and it often takes years to bring it out.

Breeders have risen in the breeding world to a considerable prominence, and have fallen out of sight just as quickly, because they were slaves to pedigree. A pedigree is only a piece of paper; it only represents past achievements by perhaps leading breeders—but it is no guarantee of the future. The crossing of strains, so absolutely essential to development, is a delicate and an uncertain affair, the results of which can only be learned by experience.

And then, the third side of the breeding triangle is the farm on which operations are carried on. On the farm are produced most of the feeds, and the character of the farm more or less dictates the character of the feeds on which the herds exist.

Certain soils are often deficient in phosphates that the animals produded on those farms require that element in some other form, and chewed up boards to secure it. This is a clear instance of a truth that is not always so clear. The more fertile, and better balanced the condition of the farm, the greater are the prospects for success in breeding operations; and, furthermore, the physical condition of the farm must be suitable or disease and sickness will run through the stock.

"NEVER BELONGED TO ANYTHING"

Such was the reply given by a well-to-do Manitboa farmer the other day to a friend who invited him to become a member of an association. He believed in the simple life. Quietly industrious, living within his sphere, minding his own business, he had been in his own estimation successful and saw no need of joining an association when in the past he had "never belonged to anything."

But what a narrow unsatisfying life he had lived. The great currents of world thought that had refreshed the souls of other men had flowed by while he was breaking and sowing and reaping. His life had closed him out. The generous enthusiasm of those who labor for redress of wrongs and the amelioration of the conditions of life he had never felt. The splendid human fellowship of those who link hands with others for the realization of noble ideals he had never shared.

* * *

There is a big revival in the sheep industry all over the Maritime Provinces. The continental prevalence of high wool, mutton and lamb values has placed the sheep business in a new light. The result will be that this phase of animal husbandry will contribute materially to Canada's food and clothing supply. It will also add stability to our systems of farming and play an important part in the more complete utilization of our agricultural resources.

THE MENTAL PROCSESES OF A STOCK JUDGE

As the season for Fall Fairs is near at hand our readers who will enter stock in the various competitions will be interested and should for the following qualifications in the men who will be responsible for the placing of awards.

Discriminating breeding involves, among other things, careful selection of the animals to be bred. This selection implies that the judge has a mental picture of the animal he wants, knows the limitations of the stock with which he deals, is able accurately to compare actual with ideal characteristics and to decide which combination of characteristics is most in harmony with the ideal. Or, since no animal is perfect, he must decide which combination of defects detracts least from the sum total of ideal qualities.

Judging should be conducted as to render itself a factor in increasing the usefulness of domesticated animals. Because some farmers have not seen how stock judging can be a distinct asset, and because some judges have disregarded the practical place of stock judging in the development of agriculture there has grown up a lack of harmony between the farmers and the judge, resulting in a variation in the types of animals considered ideal by the farmer and as approaching ideal by the judge. The discord is to be regretted. Farmers can improve their stock by introducing into their herds the blood of animals judged by experts to be good breeding stock, and by making use of the facts demonstrated in the breeding of the selected animals. On the other hand the judge should keep in touch with the commercial side of stock-raising.

The best judges are prophets. Looking back from the present, we would say that he was the best judge seventy-five years ago who selected as the finest animals, not those which would have taken championships had they been shown today, but rather those which were a marked advance over the stock of that day toward what is considered best today. Probably no judge of that day pictured such animals as are winning today, but the best judges and the best progressive breeders certainly were looking into the future when they selected the foundation stock of their herds. The great judges of the past have been leaders in the breeding ofanimals. And the best judge of today is a leader also, not a dictator nor a blind follower of fashion's decrees—an idealist, but not a mere dreamer.

A good judge is both born and made. Love for all animals, keen preception of variations, ability to size up the whole animal as well as to criticize component parts must be ingrained qualities. These qualities are made more sensitive through proper training. The judge must be strong willed. He should have control over his temper and not too quick to take offense. A grudge against an exhibitor, or displeasure with an attendant does not alter the characteristics of the animal which the exhibitor or attendant is showing. The judge must be honest—honest with himself as well as with the animals and the exhibitors. His mind must work logically that he may accurately correlate the sense impressions which sight and touch impart. He must be able to carry his thoughts to a logical conclusion upon which his decision should rest. That decision once made, he should have the courage to defend and maintain it. In order to do this he must be capable of clearly and forcefully presenting the reasons for his convictions. Independence of judgment is an indispensable trait. The judge at a fair is as closely criticised as the animals in the ring and the best judge in show circles is he who keeps his poise in spite of contrary opinions, insinuations and the dictates of fashion.

A successful breeder, feeder, or exhibitor is a good judge in so far as his judgment is concerned, and if he be able to express his reasonings and is otherwise qualified, his services are more valuable than those of a less experienced man. Quite often, however, such a man is biased toward the breed or type with which he works, and his knowledge of the other breeds, while extensive, may be limited in comparison to his knowledge of his favorite breeds. The wider the judge's experience the more effective will be his services where small shows, where the judge makes the awards on several types of animals. The deeper and longer the experience with some particular breed the more valuable will be his judgment at large shows, where specialists are demanded.

The judge should show himself willing to explain and discuss not only disputed points but all other questions which his time allows him to answer. He should be familiar with the tricks of the showring and with the deceptions commonly resorted to in exhibiting animals at better than their best.

When sure that his senses have registered aright, the judge makes a preliminary decision, then challenges that decision to make sure of his choice, and finally, before announcing his placing, fortifies himself with arguments with which to defend his convictions. This done he pushes back his hat, leans back against the railing, or folds his arms and announces, "Gentlemen, I place the animals in this order because———"

It is not at the showring that the most important judgments are passed. The breeder of live stock in surveying some animals which may be of value in upbuilding his herd and the purchase of which he is contemplating is facing a greater problem than if those animals were being judged at a fair. It is because showring decisions are, or ought to be, guides in the selection of breeding stock that they are in themselves of economic value. Showring competition is, however, one of the greatest incentives toward better breeding and affords an event of common interest to all live stock enthusiasts.

The beginner, finding his judgment at variance with that of his instructor, is apt to get discouraged or obstinate and to dismiss the matter with some such philosophy as this: "Judging is only a matter of opinion. Everyone has a right to an opinion and one man's is as good as another's. I may be as much in the right as the next." But if the beginner attends any gathering where live stock is displayed and where a number of breeders or feeders are in discussion and there carries his own philosophy to a logical conclusion, he will be forced to admit that judging is more than a matter of opinion. He will find that there is a preponderance of opinion in favor of a few animals. That not all agree on one individual as the best is largely due to a difference in ideals. Now if one man's opinion is as good as another's and the great majority of opinion coincide, there must be reason behind the fact. And since the reasonings of the majority resulted in the same conclusion it is more than probable that the basis if their reasonings was the same.

The beginner's first task is to comprehend this basis. The basis is the correlation of form to function. The beginner should familiarize himself with the anatomy of domestic live stock and be able to naame the more prominent parts. To this end the scorecard is used. It divides the animal form into segments and assigns a value to each, sub-dividing each into component parts. In using the scorecard the ideal animal is the basis of comparison. The ideal must be kept clearly in mind—not only the ideal animal as a whole but the ideal characteristics of each part. The scorecard study is analytical in nature.

The point placing card advances the student a step further, in that several animals are compared, the basis still being the ideal. Point placing is still analytical rather than comparative. The animals studied should show marked contrast in form so that the student may fully appreciate the fact that animals do vary.

Analytical studies give way to competitive comparlson of animals. The basis of comparison is utility. Though the ideal must always be carried in mind as a reference, where the contestants approach equality as compared to the ideal the final judgment is reached by balancing one contestant against the other with respect to their suitability for a definite purpose.

Practice makes perfect. Conversation with breeds, feeders and other well-informed stockmen reveals what is being emphasized from the commercial standpoint. The study of pictures helps to fix in mind breed types and desirable or undesirable features, but actual obesrvation of living animals in competition is the greatest aid in developing sound judgment. Reading keeps the judge abreast of the times, but far-reaching benefits from stock judging arise from the judge's being a little ahead of the times.—R. R. Benson in Breeders' Gazette.

PRODUCING GREATEST FLOW OF MILK WITH LEAST POSSIBLE EXPENSE IN FEEDS

The whole subject of balancing and using rations for farm stock is one that the every day farmer knows is vitally connected with the profit or loss as shown on the balance sheet recording his anual business on the farm. The methods of rationing gathered from the experience or practises of some who show a measure of success, are as a rule the guide to the rank and file in farming communities in the art of feeding. The rough and ready balancing and feeding of rations must in almost every instance lead to waste in food, but it is only when feed prices have reached present high levels that the average farmer has been forced to seriously consider the subject. Tables of the composition and digestibilities of foods, as well as tables of standard rations, are not largely studied by farmers in general, but it is becoming of the utmost importance to the welfare of the industry that these vital details in farming business be studied and better known. The agricultral coleges and experimental farms are fulfilling a high place in agricultral economics, and their experience and research is showing that meantime the feeding of live stock is a science of greatest import to the profitable production of food, and therefore to the interest of farmers. To do things in a scientific way is only to do them in a common sense way, and common sense is a product of intelligent interest.

Another leading factor in feeding animals besides a balanced ration is the tact of observation which every feeder must cultivate to gain a knowledge of the individuality of each animal under his care.

Hay and Fodder

The only coarse fodders containing a sufficiently high proportion of protein for use alone, for satisfactory growth, or normal milk or meat production, or energy in horses, are the hays, made from pure clover or alfalfa, and only these when it is possible for the animals to consume enough of them. Meadow hay, in which clover is absent, has a very poor showing in protein, only about three pounds in every hundred weight of hay, clover and alfalfa showing in analysis, 10 and 11 pounds of digestible protein. Of the straws, pea straw is the best. The farm grown grains, oats, barley, wheat, are all deficient in protein, though rich in carboydrates.

Ensilage, Roots and Grain

Corn ensilage and roots are excellent for supplying carbohydrates, but are deficient in protein, though if used with clover or alfalfa hay make well balanced rations for store cattle, dry cows and ewes. Oats is a well balanced food in themselves, but when added to poor hay and roots do very little to improve the balance. Barley and wheat are also low in protein, and unless balanced by cakes, gluten and oil meals are wasted when given with poor hay, roots or ensilage. Peas are, however, rich in protein, and can be used with meadow hay, roots or ensilage to make a well balanced ration, that will economically use up these low class forage crops.

Highly Concentrated Feeds

In buying concentrated feeds it is advisable for the buyer to get the correct analysis of digestible nutriments contained in the feed. A point worth noting in this connection, and one that shows the value of exactly knowing what is contained in the purchased feed, is, that a cake or meal containing 30 to 40 per cent. of protein will balance twice as much hay and other similar feeds, as a meal or cake containing only 15 or 20 per cent. protein. Half as much meal is only required to balance a given ration when the meal is of a higher percentage.

This is a point worth remembering, for after all the value of a concentrated food to the animal entirely depends on how it balances with the coarse foods given with it, so that the whole ration supplies the animal with the constituents it requires in the proportions in which they can be used to the best advantage. Such properly balanced feeding always gives the best results, and when it is compared with cost, is also most economical.

No farmer can afford to overlook this point in rationing when the price of feedstuffs are so high. The best results among farm stock cannot be achieved without them, and a waste of carbonhydrates in farm grown feeds is the result. Without some consideration to this subject and without some skill in this department, much loss will be occasioned in the effort to gain greater production, and much gain where judiciously and intelligently used.

Bulk in Feeds

A sucessful ration must contain not only sufficient nutriments to meet the needs of the animal, but it must be bulky enough to satisfy the appetite. If animals do not receive sufficient bulk to distend their digestive organs, they are not satisfied and will not do well. Bulk, therefore, has a commercial value. It would not pay to feed farm animals on concentrates alone, even if the required nutriments could be supplied cheapest in that form.

Assuming that the same principle holds good in human nutrition, this shatters the theory some persons indulge in, that ultimately a person can carry a full meal in a small capsule in his vest pocket. If it were possible to pack enough nutriments into a small capsule to last from one time to another, a person would still feel hollow after eating it, and would long for something to fill up on. Very concentrated foods will not come into style until digestive organs have been reduced in size.

Rationing for Maximum Production

It is very difficult to give a fixed ration, as the individuality of the cow or other animals, is a factor in the reckoning, as well as the skill of the feeder in handling them. It is only possible to cite a ration in a general way, which under ordinary conditions should make good returns.

A mixture recommended and practiced by successful dairymen is made up as follows:—400 lbs. of a high carbohydrate concentrate as ground barely; 200 lbs. of ground oats or bran, 100 lbs. of high protein concentrate such as oil meal or cottonseed meal. Under practical conditions cows should get one pound of the mixture for every 3 lbs. of milk they give. This of course when the best quality of hay is given, and along with it ensilage at the rate of 30 lbs. per 1000 pounds live weight of the cow. The skill of the feeder is, however, shown in the amount of feed he can induce the animal to consume, make good use of, and still maintain the herd in good health.

HORTICULTURE

SEED PRODUCTION IN APPLES

Introduction

The study of seed production in apples reported in this article grew out of observations indicating an apparent direct relation between numbers of seeds and size of fruit. The examination or large numbers of apples shows that the range in the seed production of individual apples is from 0 to 27—from no seeds to more than two and one half times the normal number—and that as a rule large apples produce more seeds than do small apples.

Seed production is the direct result of fertilization, and full fertilization depends upon bringing together varieties that flower together and that are congenal in all respects. This suggests the possibilitw of associating varieties in orchards in such manner as to approximate the maximum of seed production and thus secure that increase in size of fruit which would mean greater production. Valuable scientific as well as economic results would attend the successful development of such a system of association of vareities, but the immediate attainment of results that seem possible is not expected, for there is much yet to be learned both as to seed production and as to the affinities of standard orchard varieties.

Seed Production Records

As a basis from which to judge the performance of apples and crabs in seed production, records were taken from 28,054 individual apples. Thirty-two orchard varieties were represent-by 21,412 fruits, and twenty-five species and varieties of the genus **Malus** were represented by 6,642 fruits. This latter is strcitly crab group; noie of the species or varieties have any economic value other than as ornamentals. Most of them approximate the wild oriinals. The fruits of all but two of the orchard varieties were divided, on the basis of size, into two groups, a group of large apples and a group of small apples, in order to determine the relation between size of fruit and seed production. Fruits of the crab varieties were so uniform in size that no division into size groups was attempted.

Records obtained from the fruits examined suport the view that fruits of orchard varieties develop seeds in greater numbers than do fruits of the crab-like forms of the genus **Malus.** Further, they show that, as between the size-groups, the groups of large apples produced more seeds than did the groups of small apples. The differences between these three classes are as follows:

1. Average seeds to the fruit for 12,912 apples of large size, representing thirty-two varieties, 8.27.

2. Average seeds to the fruit for 8,500 appls of small size, representing thirty varieties, 7.21.

3. Average seeds to the fruit for 6,642 apples, representing twenty-five crab-like forms of **Malus,** 4.22.

Orchard Production

Seed Production.—Some varieties tended to concentrate within the assumed normal af ten seeds to each fruit, as was the case with Arkansas lacks, Grimes, Fameuse, and Rome; others tended to scatter the production over a wide raneg, as 1 to 27 in Shockley, 3 to 21 in Rhenish May, and 3 to 19 i nWinter Rambo. Distribution of seed production in its relation to the full normal content of ten seeds to each fruit is of interest as showing the extent of departures from normal in both directions. Among the 12,912 apples of large size were 1,610, or 21.5 per cent. of the total, each having the normal of ten seeds; falling below the normal of ten in seed production were 8,913 apples, or 69 per cent.; and with seed production above normal were 2,839 apples, or 18.5 per cent. Of the 8,500 small apples, 1,020, or 12 per cent, had each the normal of ten seeds; 6,786 apples, or 79.84 per cent. , fell below the normal; and 694 aplpes, or 8.16 per cent, had numbers of seeds raning above ten.

Number and Distribution of Carpels

Among the apples examined, 789, or 3.68 per cent., were found to have numbers of carpels other than the normal of five. Increase in number was more frequent than diminution; 129 aples had les sthan five carpels and 660 had more than five.

Size of Fruit in Relation to the Per Centaeg of Ovules Developed Seeds

Record was made of contained ovules, and percentages of ovules developed as seeds were computed for fruits of both size-groups of twenty-one varieties. In all but three of the varieties the numbers of ovules present in the groups of large fruits were higher than in the groups of small fruits. The percentages of ovules that developed into plump seeds are, perhaps, the best gage of the relative seed-producing capabilities of the two size-groups. Of the twenty-one varieties under consideration, all but one had the higher percentages of seeds developed in the groups of large apples. For all varieties the percentage of ovules developed was 74.5 for large fruits and 67.36 for small fruits.

Crab-like forms of the Genus Malus

The fruiting forms of the genus Malus included in the record of seed production number twenty-five. The aggregate of fruits examined was 6,642 varying for the different lots from 22 for Malus fusca to 1,200 for Malus Ringo sublobata. M. fusca was the only form represented by less than 100 fruits. The average weight for all fruits was 9.96 grams; five of the forms had fruits which averaged less than one gram in weight, and four, besides the two grams Hyslop and Soulard, had fruits that averaged above 10 grams.

Seed Production

Seed production ranged from an average of 13.2 seeds to each fruit for the 22 fruits of M. fusca to 7.8 seeds to each fruit for 100 fruits of M. Malus flore pleno. The general average for all fruits was 4.22 seeds to each fruit.

Number and Distribution of Carpels

There were wide differences among species in number and distribution of carpels; the range in numbers was from 2 to 12. Two fruits of M. Arnoldiana and one fruit of M. Sargenti had two carpels each. At the other extreme, two fruits of M. spectabilis had respectively eleven and twelve carpels each. Considering all fruits, 68.72 per cent. had the normal five carpels, 22.34 per cent. had numbres of carples less than five, and 8.94 per cent. had numbers of carpels in excess of the normal.

Number of Ovules

It developed in examining the fruits of the crab group that most species held to the rule of two ovules to each carpel with great regularity. In twelve of the forms there were no departures in either direction from the expected normal. The total of ovules above normal was 421 distributed in 158 fruits; of this number 300 were found in fruits of M. spectabilis and 81 in fruits of M. Malus flore pleno; the remainder was distributed among thirty-five fruits of seven species. Of all ovules found, 43.3 per cent. developed as seeds.

Comparing orchard varieties with crab-like forms of Malus, it is found that production of ovules in excess of normal is of much more common occurrence among orchard varieties than it is among crabs. Bringing together the percentages of ovules developing as seeds in the different groups, it is found that for large fruits of orchard varieties this percentage is 74.5, for small fruits of orchard varieties 67.36, and for crab-like fruits, 43.3.

Seed Production Under Controlled Pollination

Records of ovule and seed production for 3,861 fruits derived from controlled pollinations were tabulated. This tabulation does not indicate any marked superiority in seed production of fruits developed from flowers artificially pollinated over fruits from flowers open to natural agencies for transfer of pollen. Further studies are to be made, but the work thus far has given a rather definite impression that whether the pollination is open or controlled makes small difference in the percentaes of ovules that develop as viable seeds.

Conclusions

1. From the foregoing study of seed production in apples it appears that the average number of seeds to each fruit is almost twice as great for orchard varieties as for fruits from crab-like forms of Malus. Dividing fruits of orchard varieties into two groups on the basis of size, it further appears that large apples exceed small apples in seed production, altho the difference is not nearly so great as is the difference in seed content between orchard varieties and crab-like forms.

2. The range in average seed production as exhibited by different varieties is wide with both orchard varieties and crab-like forms.

3. Departures from the normal of five carpels to each fruit occurs with both orchard varieties and crab-like forms, but are much more frequent with crabs than with orchard fruits.

4. There are wide differences among individual varieties and species in seed-producing capacity, and the range in numbers of seeds in individual fruits is also wide.

5. The assumed normal of ten seeds to each fruit is likely to occur in a small percentage of orchard fruits but rarely occurs in crab-like forms.

6. Capacity to produce seeds appears as a varietal characteristic.

7. Parthenocarpic fruits occur in orchard varieties and in species of Malus, but not in very great numbers.

8. There is great regularity in the appearance of ovules in normal numbers, that is, two in each carpel. Few cases of suppression of ovules occur; numbers in excess of normal are more common among orchard varieties than among crabs.

9. Comparison of seed production in fruits developed from flowers open to pollination by insects and inf ruits from hand-pollinated flowers brings out onl ysmall differences; apparently seed production is not dependent upon the manner in which pollination is effected.

10. Considerable differences appear in seed production of individual fruits and of particular varieties, but averages of groups warrant the conclusion that the more highly developed orchard varieties exceed crabs in seed production and that, as between large and small fruits, large fruits produce the greater number of seeds.

(By Charles S. Crandall, Chief in Plant Breeding, University of Illinois)

STRAWBERRY DISEASES

In the following notes there are dealt with the five most prominent strawberry diseases in Ontario. It is hoped that the hints for control given may prve helpful to many whose plants are affected by one or more of these diseases.

Strawberry Mildew appears during June and early July. It is due to a fungus which grows mainly on the under sides of the leaves, and may be seen there as a white, webby or frost-like coating, usually rather scanty in amount. It causes the leaves to curl upwards, and a field which is badly affected has a peculiar whitish cast, due to this curling. Later on the lower surfaces of these curled-up leaves which are exposed to the sun are likely to turn purple or die at the edges, and when the leaves are badly attacked they may be totally destroyed. Besides reducing the feeding power of the leaves, a very seriou seffect of the Mildew is to allow the hot sun to penetrate through the leaves so that the fruit which ought to develop in a comparatively cool, shaded position is exposed to dry, hot air, which shrivels the fruit and prevents it from reaching normal size. The fungus also attacks and rots the fruit.

The Mildew is rather erratic in its occurrence. In some years it is almost absent and other years very prevalent over large areas. It develops most rapidly in warm and moist weather and will hardly spread at all when the weather is dry and hot.

Methods of Control

The most useful means of combating Strawberry Mildew is in the use of ordinary sulphur, which should be applied to the rows when the first symptoms of mildew noted. The sulphur may be applied either by using a dusting apapratus, by shaking through a fine sieve, or by putting it in a coarse cottonbag and pounding the bag as it is carried over the rows. Since it is the fumes of the sulphur, which are produced in the hot sun, which are effective against the disease, it is not necessary to cover every leaf with the dust, as has to be done in spraying. One feature of this treatment should be noted: If the sulphur is applied too close to picking times the fumes are apt to be rather irritating to the pickers on a hot day.

The Roof that lasts a lifetime

Fire, Storm, Wind and Lightning Proof

PEDLAR'S OSHAWA SHINGLES

THE ideal roofing for your home. Cannot burn, rust or decay. When properly grounded, a roof covered with Pedlar's "Oshawa" Shingles is immune from damage by lightning. Such a roof will last a lifetime without need of repair.

Leaf Spot

The Leaf Spot disease is often very damaing to strawberry plantations where it is allowed to become jrevalent. As the name indicates, spots occur in the laf which are purple in color at first or with grey or white colored centres and a purple border as the spots get older.

Measures of control should begin when setting out the plants. Select healthy young plants and remove any spotted leaves from them. They should be sprayed with Bordeaux mixture 4-4-40 shortly after they are set out, and the leaves should be kept covered with the same mixture by two or more sprayings as needed throughout the growing season. In the second year they should be sprayed before the blossoms are out with the same material. After the fruit is picked another spraying of Bordeaux mixture may be given, or else the leaves should be all mowed after picking, and when dry burned as they lie.

Root Rot

During the last few years a great many strawberry plants have been lost and many plantations badly damaged by a peculiar "rot" of theroots, which is noticed during the spring and summer months. The palnts which are worst affected die early in the spring and others survive only till blossoming time or until fruits are being formed, when they gradually shrivel up and die. It is suspected that the injury is mainly due to winter, although there is some evidence for believeing that soil fungi may also play a part in aggravating this trouble.

It has been found that when young transplants are taken from a badly affected field early in the spring they are likely to die and result ina poor stand. It is, therefore, advisable wehn setting out a new plantation to examine theroots carefully. The roots may be browned on the outside, but if the small cord-like centre is still white and moist they are still uninjured, but if the centre cord-like part is also browned, then these roots are dead.

It is encouraing to note that several cases have been observed where plantations which were rather seriously affected one year, recovered and did well during the following year.

The only conrtol measure that seems necessary in thi scase is the protection of the plants from winter conditions. In either case, however, the remedy is a mulch of strawy manure or leaves applied in late fall.

Fruit Rots

The two most important rots of strawberry fruits which have been noted are the Dry Rot and Leak. Both of these occur in the strawberry regions of Ontario, in some cases to a considerable extent. The symptoms and method of control for both are clearly given in a reecnt article by Dr. C. L. Shear, of the Fruit Disease Investigtaions Branch at Washington. His statement is quoted as folows:

"The importance of the diseases of strawbery fruits is not generally recognized by growers because they rarely see the fruit atthe market. These diseases are, however, of great importance, since they injure the keeping quality of the fruit and thus reduce the returns to the grower, shipper and merchant, and also increase the cost of the berires to the consumer. No plant diseases cause more serious losses than those which decay the ripe fruits and thus destroy food which has been produced at great expense and labor. A careful study of the diseases of strawberry fruits carried on by the Office of Fruit Disease Investigations during the past three years has shown that the two most important diseases may be very largely reduced by means which are within the reach of every grower.

Dry Rot

"Dry Rot, caused by a grey mold (Botrytis sp), is a field trouble and is particularly common and destructive on the fields which are unusually wet tither from excessive rains or because readily recognized by thefact that the berries become rather firm and somewhat discolored. Berries of any age, whether green or ripe, may be attacked on th evines, and frequently the grey, powdery mold is seen growing on the outside of the berry. Not only berries, but at times leaf stems and blossoms, are attacked by this fungus.

"While the grey mold fungus grows rather slowly on ripe berries, and so is not of great importance after picking, it may become very conspicuous, due to its ability to grow at the temperature o fa refrigerator car. This characteristic enables it to develop on the top of the load, so that it is very noticeable when the car reaches the market and is being examined by buyers, a fact which frequently results in serious reduction in price.

"The only effective method of reducing the sprad of this disease in the field is by proper drainage. Dry Rot can be and should be largely eliminated as a cause of loss after pickin by proper sorting. Diseased berries should be thrown out by the pickers or packers.

Leak

"Leak, caused by the common black mold (Rhizepus nigricans), is by far the most common and most destructive diesase of ripe strawberry fruits. It is characterized by a rapid softening of the berry and the escape of much juice. This characteristic makes it particularly conscipuous on the market where boxes and even crates are badly strained, giving them a most unattractive oppearance. Moreover the fruit soon settles in the basket or box and is unsalable except at a grcat reduction.

"Study of this disease has shown that black mold can enter strawberries only when they are injured; thus one sure method of reducing loss is to handle berries carefully, so that they may be injured as little as possible. Black mold rows very slowly if at all below 50 degrees Fahrenheit, but very rapidly as the temperature rises above this point. Strawberries should therefore be kept as cool as possible.

"One simple method of keeping down the temperature of strawberries, and, one which is available to every grower is to pick the berries as early as possible in the day, before they have been warmed up by the sun's heat. This should be done even if the berries are wet, as experiments have shown that it is much better to pick berries cool and wet than to wait until they are dry and warm. In any case strawberries should be placed in the shade as soon as picked and protected from the sun by a light cloth while being hauled to the station. ark, heavy canvas or oilcloth retains the heat and hastens the decay of the fruit.

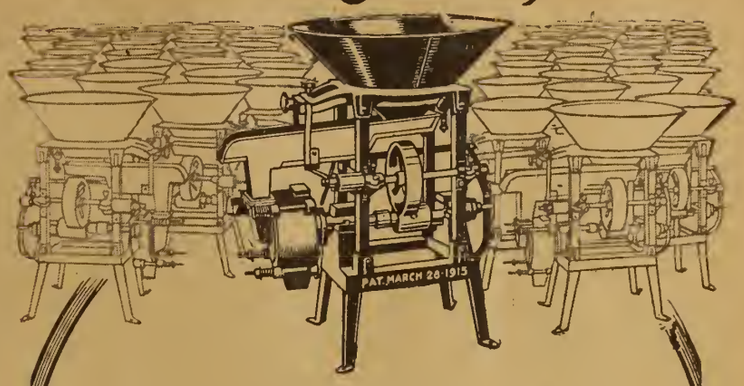
"In some sections of Florida certain rowers regularly practise washing the strawberries before they are picked. In case this method is followed strtwberries should be packed wet rather than allowed to dry, even in the shade, as experiments have shown conclusively that this drying greatly increases the amount of rot."

(W. A. McCubbin, Field Laboratory of Plant Pathology, St. Catherines, Ont. in Canadian Horticulturist.)

FALL CULTIVATION FOR THE ERADICATION OF WEEDS AND CONSERVATION OF MOISTURE

The eradication of weeds withour recourse to summerfallow or the use of hoed crops is the problem confronting the farmer in Central Alberta. In this region summerfallow is not practical, particularly in the areas of black loam soils, for the reason that too much nitrogen is liberated by the frequent cultivation with the result that the crops lodge, do not fill properly, nor mature as early as if less growth had been promoted. Hoed crops at the present time are not practical on account of the high cost of labour and the relatively large percentage of the farm which would annually have to be included in this class of crop.

Over 1500 Sold and Not a Single Complaint



That's the Proud Record of the M-RE GRAIN GRINDER the Grinder with the Emery Wheels

Let us send you an M-Re Grain Grinder to use and test for a week. During that time you can grind grain for your own home use, your live stock; or crack corn for your poultry. If you are not more than pleased and satisfied with the result of this free week's test, simply ship it back. If the M-re Grain Grinder was not so good as we say it is, we could never afford to make this offer. But we know it to be the only Grain Grinder you will ever use once you have tried it. Over 1500 machines have been sold already and we have yet to hear of one single complaint.

The MRE GRAIN GRINDER

is the only Grain Grinder using emery wheels instead of steel plates. Steel plates cut and slice the grain. Emery wheels grind and crush the grain just like the old fashioned mill stones; thoroughly and completely and produce a high grade chop. The water test will give you positive prove of this. Emery wheels can be dressed in a few moments and be as good as new while steel plates must be replaced when dulled. The M-re is the best and most economical grain grinder on the market, the one you will buy once you try it. The M-Re is built for service. Only the best materials enter into its construction—it is solid, compact, portable, and works without vibration.

Send for samples of chop made with the M-Re. Made in 5 sizes.

A booklet illustrating and describing the M-Re Grain Grinder will be sent upon request.

You can have A FREE TRIAL on your own farm

AD. NO. 5

Under these conditions, full cultivation of stubble land with the object of encouraging the germination of weed seeds offers the best opportunity of controlling and eliminating weeds. Beginning in 1908, the practice of discing immediately behind the binder has frequently been followed, and in consequence land which in 1907 produced thirty-three per cent of its total crop as weed seeds does not now produce more than five per cent. of weeds, while no season's crop has been lost in the interval through the use of the summerfallow. The advantage of discing immediately behind the binder as compared with discing after the grain has been shocked consists in the fact that all of the land can be disced, and the moment the field of grain is cut the discing is completed. Such discing has the dual effect of providing a shallow seed-bed in which weeds germinate freely, and of preventing the evaporation of moisture from the land newly exposed by the cutting of the crop. By ploughnig such land as soon as the grain is threshed and following with the packer, a second crop of weeds can be germinated in favourable seasons. The packer does the most effective work if used immediately after the plough, both as to its cultural effect on the land and in conserving moisture, and on heavy black loam soils will leave the land in good condition for germination of weed seeds.

No fall ploughing should be done to a depth less than six inches, since it should be remembered that fairly deep ploughing brings returns far beyond the extra cost of turning the additional depth.

Where the fall ploughing of sod is practised, it is wise to do this work as early in the season as possible, preferably the latter part of August or early in September. Six horses will handle a two-furrow, fourteen-inch gang plough in this class of land, and if the furrows are carefully turned to a depth of at least six inches, the land packed, double-disced and drag-harrowed, the packing at least being done daily and the other work within a week of the turning of the sod, this cultivation will be found equivalent to a partial summerfallow and quite sufficient to insure a maximum crop for the black loam areas.—G. H. Hutton, Superintendent, Experimental Station, Lacombe, Alta.

Cultivation of the soil in the autumn preparatory to spring planting is advantageous; it makes earlier planting possible, and leaves the soil in good condition for the roots of the young trees.

DAIRYING.

DAIRY CATTLE IN BIG DEMAND AT CLOSE OF WAR

One time, I remember, when I was a youngster at school, the teacher was telling the scholars about the different kinds of animals there were. It was a lesson in natural history, and she told about lions and tigers and other wonderful and strange creatures. After she had finished, she asked all of the pupils indidvidually what animal seemed to them the most wondeful. She received all sorts of names; most of them were names of strange and curious animals. There was one little fellow who had done a lot of listening, but had kept very still and had not talked about what he had heard. She asked him:

"William, what animal do you think the most wonderful?"

"The cow," he answered.

The way everyone laughed at this unexpected answer, made the poor boy hang his head in shame.

But today that same little boy, now grown to be a man, has shown that he was not very wrong when he stated that he thought that the cow was the most wonderful of all animals. He has one of the finest herds of purebred cattle, and his farm is one of the most fertile and while he has not the wealth of Rockfeller or Morgan he has independence and happiness which great wealth cannot always buy. And all of this has been acquired through the help of cows.

I have in mind two different persons who started farming about ten years ago. Each had about the same sort of a farm to start with. And each had the same amount of capital to begin with. In fact, they each started with the same. One of them stated that he was not going to be bothered with cows; they "tied one down too much." He made the principal method of his farming raising crops to sell. He planted large acreages to potatoes and used commercial fertilizers. At first he had more money than the other man. But by gradually taking out of the soil its fertility in the form of crops, and selling them, he is now unable to raise much on his farm. He is at present teaming for a living and agriculture is only a side line.

The other fellow began with a few cows. Made dairying the foundation of his farming. He gradually worked up his mowings and fields with the manure which his cows made. Little by little he added new stock to his herd and after getting a pure-bred bull he has raised a nice herd of grade cows. He has not sold off the fertility of his farm by selling grain or other crops or hay. These take away the fertility quickly. But by selling milk or butter there has been very little taken away from the farm. And, today this man has one of the best farms around and he and his family have some of the good things of life. He lets cows work for him and they have "made good."

Cows are the foundation of progressive agriculture. Successful agriculture is the foundation of a powerful and prosperous nation. In proportion that the live stock is sold off from any country, then poverty and failure takes place. On the other hand, wherever the farmers are successful, which is principally through live stock farming, there is found happiness and progress for everyone.

When a farmer has a stable full of nice cows, there he has beings working for him at all times. A cow is one of the busiest of animals. Night and day she is taking crude material in the form of hay and grain and silage and converting these into valuable food products such as milk and butter. She knows no holidays. At times she presents to her owner young which go to make up the herd of the future cows, etc. All of these are valuable.

Even when the cow gets too old for dairy purposes, she is sold for beef, as a final source of profit.

But, there is another thing which the farmer gets which is worth much. That is manure. That is made night and day and that is the foundation of the fertility of the farm. That is a fertilizer which is truly valuable. Manure makes the light soil firmer, makes the heavy soil more mellowi Puts humus into the soil and holds moisture in dry seasons, and in the early planting days retains the heat of the sun which makes the soil keep warmer for the early crops. And, unlike commercial fertilizers, it stays in the soil for a number of years.

When one sells from the farm hay, corn, wheat, etc., there is taken from the farm in fertilizing ingredients $7 to $10 worth for each ton sold. With dairy products there is only about $2 or less for each ton. Where one ton of milk is sold there are ten to twenty of the other products for the same amount of money received. If butter is sold there is only 50 cents worth of fertilizer taken from the farm for each ton. With this and milk a large per centage is taken from the air through the feed consumed. So, with dairying there is practically no loss when its products are sold, as the reverse is, with grain or hay and other crops.

While the exepnses are very great at present in keeping live stock the value of course, of cows, is fifty to seventy-five per cent. greater than it was a few years back. There are many who are getting discouraged and disposing of their stock. I feel that this of course, is unwise. In a few years, after the war is over there will be a big demand for dairy animals, especially of the better grades. All of the countries that have been in the path of the war will need new stock. Then will the farmer that has carried his cows through these hard times get his reward. Bseides, his farm will be up in fertility, where those that have not the stock will have gone backwards. The cow is going to save the farm. And the farm that is properous (through its dairying, etc.), will help to build up agriculture and the prosperity of the nation. With the help of the farmer, the cow will do her part to win the war and make everyone who has stood beside her, and carried the dairy through, successful.

Truly, when we realize the changes that have been made in the cow from the beginning, when she gave a few quarts of milk each day, until now, through the ages of time, she gives enormous quantities of milk and butter-fat; how she has been the foster-mother of the human race, and the foundation of our fertility, and incidentally prosperity; who will not agree with the little boy mentioned at the first of the this article who said that the cow is the most wonderful of all animals.—C. E. Richardson, in Ottawa Valley Journal.

SUMMER FEEDING OF MILCH COWS

The feeding of the milch cow should start when she is dry in order properly to prepare her for the milking period. The thin cow at calving is in poor condition to make milk profitably, nor can she produce the most rugged and healthy calf. Allow the cow four to ten weeks dry period before freshening. A first-class pasture, with or without grain, according to the needs of the cow, is the best conditioner for the dry cow in preparation for the milking period. A pound of grain during the dry period is worth at least three pounds of grain fed after the cow has freshened. On poor pastures feed the dry cow green feed or silage and a grain ration composed of equal parts of any of the two following meals, bran, ground oats, ground barley, ground screenings. To the thin, dry cow feed four to seven pounds daily, even though on good pasture. To the dry cow in good flesh and on good pasture no grain whatever is necessary.

Feeding at Calving.—Special care is required in the feeding of the cow at freshening, the procedure varying with the individuality of the animal. Be sure that the condition of the bowels is normal. Constipation at this time is apt to induce such trouble as milk fever, while the opposite condition is very weakening. After calving give a tepid drink containing a handful of linseed meal. Allow to rest quietly for twelve hours, after which give a warm bran mash with two bran mashes on the second day. Feed indoors for three days, giving a limited supply of green feed or good hay. Draw a little milk three to four times daily for the first three days. Do not milk dry until after the third day, as such procedure frequently induces milk fever. On the fourth day the cow may start on pasture, but it is usually advisable to supply a meal ration consisting of equal parts bran and oats in addition thereto. Unless pastures are good, this grain ration should be continued and even strengthened with some more concentrated meal.

Feeding the fresh cow.—The cow weighing 1,000 pounds requires the equivalent of 40 pounds of mixed pasture grass, or 10 pounds each of clover, hay and oat straw for the maintenance of her body alone. To this must be added the food to supply energy and the ingredients to manufacture milk, hence meagre feeding of milch cows means light returns, and liberal feeding is followed by heavy production and a lower cost per gallon.

As a rule, milk produced during the summer months with an abundance of, pasture is the cheapest production during the year, hence the proper care of pasture is most essential. Cattle should not be allowed to graze too early or so closely that the pasture is unable to withstand drought. With a shortage of permanent pasture, spring or fall-sown grains may be used as a supplement. Fall rye may be grazed both in the fall and spring. Such annual pastures as heavily seeded oats and barley or a mixture of oats, barley and wheat, will make excellent summer pasture. With present labour shortage it is probable that these annual pasture crops are more economicol than the growing of soiling crops to be cut and hauled to the stock on pasture or in stables. However, such soiling crops as peas and oats seeded at different dates, second cut clover, corn or fall turnips fed with tops as pulled, provide an excellent substitute for pasture. Silage made from corn or peas and oats, if available, is both a superior and a cheaper substitute for pasture.

Whatever the roughage may be, the majority of successful dairymen, as a rule, feed a limited grain ration during the summer months. A mixture of equal parts bran and oats or with the addition of 10 per cent ground peas or some similar concentrated meal will give excellent results.—E. S. Archibald, Dominion Animal Husbandman.

TREATMENT OF THE MILKER

The calf's udder needs to be looked after as soon as she is born. Her mate penned with her, may suck her little teats, and start secretions that will result in a spoiled udder for her, and bowel trouble for the "wind sucker," for even a kitten that sucks on something that yields no milk but only air, will become emaciated and perhaps die. Again, colds will often injure the the bag, lying on damp or dirty floors, bruises to teats, now or after she becomes a milch cow, and forcing with concentrated feeds cause garget, as do unclean hands and unsterilized tubes.

Don't buy a hard milker or short-teated cow, or raise a heifer with abnormaly smal teats or with too many or two few; and do the first milking of a heifer with her first calf yourself, as she can often be made a hard or easy milker by careless or careful teaching from the first.

where teat joins udder, and massage downward, pressing the milk down toward the end with a firm but caressing movement. then bring the whole hand to bear with that same massaging motion, to press the milk out. Pulling with a see-saw pumping motion is not skilful milking. The idea is to massage the milk out the whole milk factory with one long, continuous pressure. Milk briskly, but not hurriedly, and milk her dry at one sitting. Leaving a drop to be stripped out later teaches her the habit of holding up her milk for Act II.

Talk to calf, heifer, and bull—not letting talk take place of dehorning, however—accustom them to your presence and voice, and make friends with them, and see that hired man and dog are friendly if they stay on your premises. If any part of a cow is scratched, especially the udder, disinfect with a good germ-killer at once and keep clean.

ARE BUTTERMAKERS RESPONSIBLE FOR MOULDY BUTTER?

A great deal has been said by convention speakers regarding the prevention of mouldy butter.

It is not necessary to give the various methods that may be followed in treating the tubs and liners before they are used. The simplest one can be carried out in every factory by even an untrained maker.

1. Clean all tubs when brought into the churn room, using hot water and brush.
2. Place all tubs and covers in a tank of boiling water for a period of 10 minutes. Then fill tubs with cold water.
3. Place all liners and circles needed for the day's pack in boiling water for at least 10 minutes; then in saturated brine until used a few minutes later.
4. Before lining the tubs sprinkle salt on the inner surface before placing liner in position.
5. Sprinkle salt on top of the butter and moisten with clean water.
6. All unused tubs and liners must be again treated before being used the following day.
7. Thoroughly clean and whitewash the refrigeratir.
8. Allow a 60-pound tub of butter to stand in the factory refrigerator for 10 to 14 days; examine closely.
9. Pasteurize all of the cream before churning.
10. Consider mold as a dangerous enemy of the dairy industry.

This is a very serious question, and must receive the attention of every buttermaker of the country. The weather during the past few months has been very favorable for the growth of mold.—C. E. LEE.

OINTMENTS AND SPRAYS TO KEEP FLIES AWAY FROM CATTLE

There is nothing that will keep flies entirely away from cattle but any one of the following mixtures will be found useful:

1 pound rancid lard, ½ pint of kerosene. Apply with hands or brush.

3 parts fish oil, 1 part kerosene. Aply with small spray pump.

2 parts cottonseed oil, or fish oil, 1 part pine tar. Apply with large paint brush.

2 ounces pennyroyal, 1 quart of olive or rape oil. Apply with brush.

In case of the horn fly, pine tar or crude oil may be plastered around the base of the horns or used somewhat diluted over the head and shoulders.—Geo. H. Glover, Colorado Agricultural College, Fort Collins, Colo.

NOVA SCOTIA CREAMERY BUTTER WINS AT WESTERN EXHIBITION

The Pictou County Dairy Company, Ltd., of Stelarton, N. S., made an exhibit of creamery butter at the Calgary Alberta, exhibition from June 28th to July 6th, and won up high in the prize list, their butter scoring 97.1 out of the possible 100 and the highest score made was 98 points The Company is receiving congratulations on the splendid showing made against the finest creameries in Western and middle Canada and also in view of the fact that Alberta for some time has been considered to be making the finest butter in Canada

This is another evidence that no finer butter can be made anywhere than in Nova Scotia.

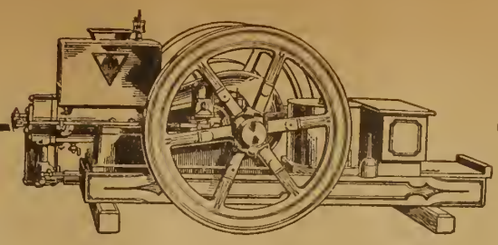
KEEPING BUTTERMILK SWEET

Some time ago a friend brought me a gallon of buttehmilk. At the time of churning she had put a quantity of water in the churn to assist in gathering the butter and, of course, this water remained with the buttermilk. After two or three days I went to get some of the buttermilk to use and found that the water had risen to the top and completely covered the milk. This gave me an idea, and after taking out what I wanted, I again covered the buttermilk with fresh water. Two or three days later I found the buttermilk as fresh and as sweet as at first. I continued to use a small quantity at a time, each time covering the buttermilk with water. I used the last of it after five weeks and found it still sweet. Since that time I have repeatedly tried the experiment and have always found the buttermilk sweet and good. Loppered milk may be preserved in the same way.

STRINGY MILK

Every year at this time we have a number of questions about stringy milk. People usually blame the cow for this condition of the milk, but in most cases the cow is not at all at fault. It is nearly always caused by a certain bacterium which when working in the milk gives it this ropy or stringy condition. Most people would feel insulted if it were suggested that the milk utensils were not entirely clean, yet usually this bacterium is found on the dishcloth, towel, or in the seams of the pails and pans. Even when these are carefully washed and scalded, the bacteria will be found somewhere along the line between the cow and the milk pan. The remedy for this condition is to boil thoroughly everything which touches the milk. Of course an exception would have to be made in the hands of the milker, but the clothes and the utensils should all be thoroughly boiled day after day for at least two weeks. We have many cases where readers reported this condition of the milk, and they could not believe that there was any trouble with the milk handling. They followed the plan of boiling thoroughly all the milk utensils for half an hour each day, and then put them out in the hot sun for an airing. When this was carefully followed out, and the stable cleaned up, the milk came back to a proper condition, and they had no further trouble with ropy or stringy milk. This is the remedy. It has to be applied in many cases, and always so far as we know with good results. Clean out the stable or stall where the cow stands, and give her a good washing or scrubbing. Keep the hands clean when milking, and boil the cloths and the tins thoroughly every day. That will get rid of the bacteria and end the trouble.

Henry Ward Beecher once said that the cow is the saint of the barnyard, and although she has few graceful lines and curves, a very awkward walk and an even worse "run," she is very charitable and self-sacrificing. And it is true that while the cow is not always a beautiful specimen of her race, yet she is much admired by all who appreciate the buttered side of their bread and the numerous other articles of food coming to us from the farm dairy. The small boy who hated to milk, when asked what he would do without cows, replied that we could use condensed milk. The homely dairy cow ought to be loved and well treated for the part she plays in feeding the world.



ALPHA GAS ENGINES

faithful as a work-horse

DEPENDABILITY is the keynote of the Alpha. It RUNS when you want it to—chugs away all day and you never need to think about it.

It's always reliable; always ready.

Why?

Because it's so simply and sturdily designed and so expertly and honestly built.

There's nothing complicated about the Alpha—no electric batteries; no delicate attachments to "keep you guessing."

Just oil it; turn on the fuel—either gasoline or kerosene—and the Alpha does the rest.

It takes a whole lot of the drudgery out of farmwork, and, in addition, saves time and fuel.

JUST ASK ANY ALPHA USER

Alpha Gas Engines are made in 12 sizes, 1½ to 28 H. P., and in stationary, semi-portable or portable style, with hopper or tank-cooled cylinder.

In case of the horn fly, pine tar or crude oil may be plastered around the base of the horns or used somewhat diluted over the head and shoulders.—Geo. H. Glover, Colorado Agricultural College.

The farmer who feeds his crops to live stock and who carefully saves and returns the manure to the soil, retains on his farm a large portion of the fertility originally removed by the crops. He also has the chance of a double profit, receiving the value of his crops through the sale of live stock and live stock products, and at the same time retaining the crop constituents on the farm as fertilizer. This is the reason why live-stock farming pays better than crop farming in the long run. A live stock farm retains its fertility and productiveness.

Just Like Starting a Bank Account!

YOU start a bank account to save money. Put Hassler Shock Absorbers on your Ford for the same reason.

HASSLER PATENTED
Shock Absorber
For Ford Cars

Hassler Shock Absorbers pay 100% interest the first year, and keep it up every year thereafter. They save one-third of your up-keep bills because they reduce wear and tear on the car. They give you more miles per gallon of gasoline because a car that rides easily and smoothly requires less power to propel it. They pay for themselves in increased tire mileage because they take the weight of the car off the tires and cushion it from every jolt and jar. 300,000 Ford Owners recognize their economic necessity. Better than any bank account, they give an actual physical comfort to riding that cannot be computed in terms of money.

10-Day Free Trial Offer

Phone, write or call for FREE TRIAL BLANK and we will have a set of Hasslers put on your Ford without a cent of expense to you. Try them 10 days. Then, if you are willing to do without them, they will be taken off without charge. Don't ride without Hasslers simply because someone discourages you from trying them. Accept this offer and see for yourself. Over 300,000 sets in use. Do it now.

LIVE STOCK.

IN FEEDING CALVES METHODS WHICH WILL GIVE BEST RESULTS

Giving a calf an extra good start the first six months of its life and doing so cheaply, is the secret of successful and economical stock raising.

No matter how good the calf at birth, it will be handled at a loss, or more or less seriously handicapped for future usefulness and profit if not fed carefully and cheaply in its early days.

The present high prices of whole milk practically exclude this product being used to any extent in calf rearing, although it is absolutely necessary for the first three or four weeks if best results are to be obtained. To discover the best substitutes for whole milk and the best methods and practices in calf feeding, a large number of experiments have during the past three years been conducted on the Dominion Experimental Farms. A few deductions from these experiments are given herewith.

I. It is more profitable to breed and rear good young stock to maturity than to purchase the average cows for sale, which are usually the animals least profitable and desirable in the neighbor's herd.

II. The cheapest way of building up a good herd is to raise it. The feed costs of good rearing in Canada range from $16.00 to $24.30 for 6 months calves, $24.00 to $45.00 for 12 months calves and $37.00 to $74.30 for 24 months heifers, the variation depending on methods of feeding, feeds available and market values of these feeds.

III. Calves of poor type and breeding are not worth rearing, but good calves properly bred will be worth at least 30 per cent, and up to 100 per cent. more than their feed cost at two years of age.

IV. Calves of good size, strong constitution and large capacity will, on the same feed, make greater growth and better gains than small, weak, narrow individuals.

V. Good rearing of calves is most profitable as shown in such results as,

Earlier maturity in size.
Earlier maturity in profitable production.
Greater production throughout the whole life time.
More valuable and in greater demand at the highest price.
Healthier stock.
More durable animals.
Better able to consume most profitably all cheap farm grown roughages and convert these into milk.

VI. The calf reared on its dam costs 25 to 50% more than the pail-fed calf, and the more productive the cow the greater will be the charges against the calf.

VII. Pail-fed calves reared to 6 to 8 months largely on whole milk, make gains which cost $14.00 to $18.75 per cwt., which is several times the cost when a properly fed substitute for whole milk is used.

VIII. Skim-milk fed sweet and at a temperature of about 90 degrees Fahr. is the best single substitute for whole milk, and may reach a value of 70 cents per cwt. or more in feeding young calves. However, skim-milk may be improved by the addition of a good cream substitute such as flaxseed jelly, oatmeal or a well-balanced calf meal.

IX. Buttermilk, if fed uniformly as to acidity and temperature, may have a slightly greater value than skim-milk. Great caution must, however, be taken to start calves at a greater age and very gradually.

X. In feeding calves to 6 to 8 months of age on rations composed largely of skim-milk or buttermilk and a good cream substitute, gains may be made at a cost of feed amounting to from $2.00 to $7.15 per cwt., this amount varying with the character and price of meal and the ruggedness and thrift of the calves.

XI. If well started on mother's milk, calves may be well reared on calf meals without whole or skim-milk. However, greater care and attention must be paid to these calves, and even so, gains cost from $5.00 to $15.41 per cwt. or nearly double the cost where some skim-milk is used.

XII. There are many excellent calf meals on the market in Canada. The Canadian manufactured meals are as good as and generally decidedly superior to imported meals, due not only to the palatability of the ingredients and the chemical balance, but even more to freshness and freedom from mustiness.

Of the Canadian made calf meals used the three which in total gains have given excellent satisfaction are Royal Purple, Gold Dollar and Caldwell's.

Providing the necessary ingredients are available, it may often be more economical for the feeder to mix his own calf meals. If properly done, the resulting gains in weight of the calves may be nearly a sgreat, and often at a much reduced cost.

XIII. In order to rear the best and cheapest cows, all pail-fed calves should be taught to eat, at an early age, cheap and nutritious farm-grown roughages and grains. The best roughages are grass, fine alfalfa or clover hay, swede turnip, mangels and ensilage. Of the grains, oats and barley are unexcelled.

To Have Better Calves

1. Give suitable feeds and avoid overfeeding.

II. Feed regularly and carefully.

III. Keep calf pens clean and freshly bedded.

IV. Avoid in every possible way all such infectious diseases as scours, tuberculosis, black leg and abortion.

V. Destroy parasites such as worms, ringworm and lice.

STOCK FOR SHOWS SHOULD BE FITTED

There are not a few exhibitors of live stock at the animal fairs who send animals into the judging ring unprepared. Many an animal has fallen out of the prize list because of carelessness in fitting it for exhibition. This is an injustice to the animal, the breed, and the industry, and a distinct loss to the exhibitor. The showyard presents an opportunity for the public of studying the improvement of cattle, and it is an advertising medium of the first order to the breeder. The greatest gains to be had in showing stock are in an educational and advertising way. The money earned as prizes does not rank among the greatest benefits; as a matter of fact, few exhibitors win enough cash to offset what must be spent while animals are being prepared for showing. Skill in showing can only be obtained by observation and practice. The home is the training ground, and the intending exhibitor should have a periodical cattle show round the barns before starting out on the fair circuit. All animals should be taught to lead, and stand correctly. The majestic step in the former adds to the personality of the exhibit, which is the first characteristic that attracts the attention of judges. The last feat, that of standing correctly before the judge, is imperative and is the most difficult to attain. Stand the animal so that any weakness in conformation appears absent. Many animals show a weakness in the top line, and dip in the back while standing. This fault is generally apt to be aggravated at a fair, owing to the tiring effects of the journey and the lack of opportunity to get the accustomed rest while in the fair barns. The expert exhibitor is alive to the defect, and knows the way to eliminate it at the inspection. A touch with his cane on the front legs tells the trained animal where to place them, and the head is held at the correct elevation, and the picture of bovine symmetry is complete. The animal and herdsman seem to understand each other, and the spectators are led to believe that the animal itself is conscious that the supreme moment has come. Some animals are nervous, timid, and hard to handle before a crowd; therefore to gain their confidence they must be taught the way they should act. An animal that is a good actor will always capture the eye of the judge, and if it is a toss-up between two animals, which to place first, the better actor will win.

The first and most necessary act of preparedness is to have the animals in perfect health; without this no show bloom is possible. They must be fed and groomed regularly. In hot weather they should be kept in the barn all day and let out at night for exercise and for the fine grass they would get to put the finishing touches on condition. To get the hair in good condition use the currybomb or hard brush, then later put on finishing touches with a softer brush and plenty of elbow grease. Soften the skin by using woolen blankets; it will also make it pliable to the touch. The texture of the skin is a true indicator of the quality of the animal throughout, and if dirty, after a careless washing in which the soap has not been cleaned out, a silky skin of good quality will feel as hard as a tanned hide and the coat yellow and lifeless. If the animal is white or has white spots on the body, the white can be made more distinct by adding osme bluing to the rinsing water.

Have the hoofs in proper shape. Crooked, overlong or misshapen toes will detract very much from the appearance of the animal, denying it the opportunity to step out with a healthy, firm step. A rasp judiciously applied will remedy the appearance, and take off the superfluous hoof that is apt to grow more quickly from good condition, and lack of exercise on hard surfaces. If they require clipping with the hoof clipper, the operation must be done months before fair time, so that the natural shape will have returned.

For smoothing the horns use a soft file or emery cloth, and bring up the lustre of the horn with a liberal use of cloth saturated with linseed oil.—James Henry in Breeders Gazette.

FALL WORK WITH SHEEP

Fall is breeding time, and as the condition of the ewes and ram at this time has a very decided effect on the character of the lamb crop both as regards number and strength, so is it a time at which the foundations for the next year's success or failure are laid. A thin, unthrifty breeding flock means that the lambs will be few and weak; an over-fat, sluggish flock will bring the same result.

Weaning.—The lambs should be weaned about two months before the ewes are to be bred again. The lambs should be provided with separate pasture. Some heavy milking ewes need to be milked out by hand two or three times to prevent udder injury. Never allow the lamb to suck again after once being separated, as the milk is dangerous to him when it has not been drawn regularly.

Flushing.—This is a term applied to giving the ewes some extra feed just before breeding time. If they are gaining in condition and ar exceptionally thrifty at this time, they are more likely to conceive at the first service and to produce more and stronger lambs. Usually, on the Western farm, there is abundance of sheep feed at this time on the stubble fields. In cases where lack of fencing, late threshing or other causes make it impossible to allow the ewes a plentiful run of stubble fields.

FARMERS AND BREEDERS

Who wish to keep their horses and cattle strong and healthy, should always have on hand a supply of

OMAZON

The Canadian medicinal stock food for Horses, Cattle, Sheep, Hogs and Poultry.

It will help to economize on feed and owing to its sovereign tonic and curative virtues will keep the stock strong, healthy and free from many ailments.

Order from your dealer. If he hasn't it in hand, he will be pleased to obtain it for you.

Standard Hand Separator Oil

MAKE IT SKIM CLEAN

DOES your cream separator skim clean? You can help to maintain its reliability with correct lubrication. But be sure to use the right oil.

Standard Hand Separator Oil is specially made to insure smooth running and uniform high-speed—conditions that largely govern thorough separation.

It is pure, highly fluid, lubricates all wearing parts, prevents seam rust and corrosion.

Sold in pint, quart, half-gallon, gallon and 4-gallon cans; also barrels and half-barrels. By reliable dealers everywhere.

IMPERIAL OIL LIMITED
BRANCHES
THROUGHOUT CANADA

some supplementary pasture should be provided. In any case, some succulent pasture such as rape or clover aftermath will be very beneficial, as soft, succulent feed of this kind is more effective in flushing the ewes than the dry pickings of the stubble. Grain feeding is not usually necessary, but in rase of pasture shortage should be resorted to rather than let the ewes run down in condition.

The Ram.—The ram should be kept separate from the ewes from about September 1st until breeding time. He should be well fed during this time so that he starts the breeding season in good condition. He should not be loaded with too much fat so as to be sluggish, but should be in good, thrifty, moderately fat condition. A little grain feeding at this time in addition to pasture is advisable. A mixture of half bran and half whole oats, is very suitable for this purpose.

The best way to breed a flock of ewes is to keep the ram separate and allow him with the flock only for an hour or so each day during which time he is watched and allowed to breed each sheep only once and a record kept of each mating. However, with labour conditions as they are in the West this is practically never possible and teh ram must run with the flock. A mature ram may be allowed to run with thirty to thirty-five ewes, or a well developed lamb with twenty to twenty-five.

It is a good idea to paint the brisket of the ram with some coloring matter that will mark the ewe at each service. If the color is changed each three weeks, one can easily see how many ewes are returning.

The date at which ewes should be bred depends on the conditions under which they are to lamb in the spring. A ewe will lamb about five days short of five months from the date of breeding. Turning the ram loose about November 1st will thus bring the lamb crop in during the last few days of March and the month of April. This is a satisfactory time on the average farm where shelter can be provided in case of lambs cóming in bad weather. Normally, only shed shelter is necessary at this time. Where sheep must lamb in the open, breeding should not begin until December 1st.

Dipping.—While not quite so essential as spring dipping, a dipping in the fall is very beneficial to a flock. They may have only a few ticks on them but if these are allowed to multiply undisturbed, they will be very numerous and cause much discomfort to the sheep before the spring dipping time arrives. A good reliable prepared dip is the best to use; the sheep should be thoroughly immersed in the solution.

EUROPEAN LIVE STOCK BEING GREATLY REDUCED

The comparative losses of live stock by the warring and neutral nations of Europe and the general effect on their meat supply may be judged from figures just given out by the United States Food Administration.

As regards meat, the Central Powers were much better prepared for the war than the Allies. Although the Allies possessed a greater total number of meat animals, the Central Powers had forty-two per cent. more per capita. This advantage amounted to thirty-three animals of all classes per one hundred population.

Due apparently to acquisition of animals by conquest, Germany has not slaughtered her home supply of live stock as rapidly as otherwise would have been necessary. There is now a practical exhaustion of animals in Belgium, Serbia and Rumania as a result of invasion, according to information from very reliable sources. In total animals the Allies have decreased their herds and flocks 45,787,000 head while Germany has reduced hers about 18,000,000—only slightly more than a third as many. The figures include cattle, sheep and hogs. Neutral nations show a total net reduction amounting to 1,412,000 of these animals. The European loss thus exceeds 65,000,000 head without taking into consideration Austria, Turkey and Russia which would, undoubtedly, bring the total to over 100,000,000.

A somewhat clearer view of the European meat situation at present is secured by reducing the number of animals to the actual amount of dressed meat they will yield. Rating cattle as equivalent to 500 pounds of dressed meat a piece; sheep forty pounds, and hogs 150 pounds, it appears that the various countries have suffered losses in their total meat assets to the following extent:

Per cent. of Loss on Meat Basis	
Allies as a group	28.7
England	12.5
Belgium	82.0
France	21.4
Italy	17.8
Germany	36.3
European neutrals	0.9

Considering the poor condition of the animals still alive and the reported reduction in live weight, the possible meat resources of Europe are obviously still further reduced.

The total number of cattle, sheep and hogs now in the United States is about 187,000,000, according to best estimates, which makes a striking comparison with the European depletion of 100,000,000 animals. Briefly, it appears that Europe has already lost considerably over half as many meat animals as there are in the United States today.

HINTS FOR THE YOUNG LAMBS

When we wean our lambs the ewes are turned out on the poorest pasture we have, to dry up their milk. Following that they are allowed to run on ordinary pasture, says H. L. Wordwell, of New York. The Shropshire is an easy keeper. After they wean their lambs the ewes are given no grain of any kind to eat; and yet their condition is first-class. In this connection I want to give a few suggestions as to how a man raising sheep should handle his lambs after they are weaned. We all know that one of the greatest troubles with raising sheep is that many of the lambs die from worms. While the weather is cool, in May and June, and the pasture is fresh, the lambs will do well enough, running with their mothers in the pasture, providing you change the ewes and put them on different pasture about every two weeks.

If a man has three pastures and is raising cows also, he may run the cows on a pasture and every two weeks take them off and put them on a new pasture, following up with his lambs on the first pasture; and so on, letting the lambs and sheep follow the cows. By the time he has gone over the three he can rotate again in the same way. Now, when lambs are weaned in June or July, it is getting hot weather. Then is the time that the worms will bother the lambs. To provide against this trouble, plow up some ground early in the season and plant the land to rape. Plant it in rows with an ordinary seeder, and give it two or three cultivations. It will soon cover the ground, and when July 15 or August 1 comes, hurdle the lambs on this rape, giving them one row of the rape in the morning, a second in the middle of the day, and a third at night. If you have 75 to 80 lambs, a row 60 to 70 ft. long will be plenty. Then put some feeding troughs upon the rape ground which they have eaten off and give them about a handful, twice a day, of bran and oats, half and half, and add to this mixture about a fifth by weight of linseed cake, cracked pea size. You will be perfectly astonished how the lambs will feed up and grow under these conditions. It is very beneficial to have a pasture adjacent to the rape field, where they can run off and on during the day. The sheep is a dainty thing, also a great weed eliminator. This rape is as clean as the salad on your plate in your own home, hence the sheep will consume every bit of rape when hurdled on it, and like it, whereas if you turn them right on to the rape field they will muss it over and a large portion of it be wasted. One more thing I want to say about this method of feeding; the ground that is thus hurdled off is thus manured by the droppings of the sheep and is in excellent condition to raise a big crop of anything the next year. Last summer we had a piece of rape of about three acres, and from 75 to 100 lambs were hurdled on it from July 15 until November 9.

HEAT IN SOWS AFTER FORCED SERVICE

While employed as swine herdsman at the University of Illinois I had charge of a very large Berkshire sow which had not farrowed and so far as I know had not been in heat for about a year. I decided to put her in the breeding crate and give her a forced service. Within a very short time after that she came into a natural period of heat. The sow was then bred about the middle of the period, and from this service farrowed 13 fine pigs. She has been breeding ever since, so far as I know. I have only tried this once, but I believe is to be a reasonably sure remedy for sows. As to cows I cannot say.—W. H. Cain, Nelson Co., Va.

Just now there are many questions about the hard crust or growth on the legs and feet of chickens. It is known as "scaly leg" and is caused by a small mite which works in under the crust. Soak the feet and legs in warm water for five minutes and then smear the crusts with one part kerosene in two parts raw linseed oil or one part oil of caraway in four parts lard or vaseline.

"The essential characteristic of Shorthorns is beef, but a beef breed that can show a herd with more than 40 cows with milk records ranging from 10,000 to 13,232 lbs. is worthy of careful consideration."—B. O. Cowan.

THE HORSE

THE HORSE COLLAR

No hores collar that is fastened at the top can ever be economical in harness up-keep, neither does it tend to be the most comfortable for the horses, or act as a safeguard against sore and bruised shoulders. The collar that is of the greatest utility to the work horse is the one that is firm, and no collar that fastens at the top and is unfastened every time it is used can remain a firm and fit article. Unfastening at the top slackens and damages the breast of the collar, and a slipping up and down movement is caused when the horse pulls. This invariably starts firing, blistering and open sores. The collar soon becomes broken into two halfs and is irreparable. At the price harness is now at and will likely reach before leather is placed at the disposal of peaceful enterprises, it is up to the farmer to exercise care how he uses the article on hand.

In the matter of reducing the cost of tear and wear in harness and horse, the collar that has no fastening buckle, either above or below, is the one that is the most economical for both the motive power of the horse and for the labor bill in harness. If the horse could express how he feels in his harness when doing his level best at pulling, he would make most comment on the collar.

How the Horse feels it.

Suppose anyone placed a rope over your own shoulder and told you to get along and pull with it as hard as you could, the chances are that you would re-arrange the rope yourself before you commenced to pull, or at least after you had gone on a little way you would have a desire to change it somewhat to fit some peculiarity in your make-up that was overlooked or unknown by the man who placed the rope over your shoulder. The horse has the same desire as you have to feel as comfortable as possible, but has no way of expressing himself and cannot readjust his collar.

It is this want of thought on the part of the horseman and the inability of the horse to fit the harness to his liking, that is the cause of all the horse shoulder sores and deterioration of motive power on the farm. When a collar is once firm and is a proved and secure good fit to the shape of the horse's neck, it is the duty of the horseman to keep it so. But it cannot be kept in firm and fit condition if it is unfastened every time it is taken off. By this operation it gets broken in texture at the breast, thus destroying the utility of the collar in a season or two, and widening it so that there is too much movement and free play on the shoulder, and consequent damage to that part of the horse's anatomy. To meet the bad effect of this process tightening of the fastening at the top is resorted to, but this method fails to meet the desired end as it does not relieve the animal at the part of the shoulder affected by the misfit.

It should be put on and off over the head, and a horse soon gets accustomed to the act and will assist to get it on. The writer never had any difficulty to train the horse to put on his own collar, when it was laid on the manger, in a way that the horse could get his head through. No heavy draft horse in Scotland is ever put to hard pulling with a collar that is fastened at the top with a buckle and strap. They find that the strap at the top allows he collar to give with pressure in pulling, and blistering and wither sores is the result. Every horse has his own collar and no changing around of collar is practised. All collars are made without any strap fastening, and have to be put on over the horse's head. They are firm and wear for many years without repair; the matter of repair in these days is worth more than passing consideration.

Taught the Vice of Balking

Many horses are taught the vice of balking through bad fitting collars; at breaking in as a rule, all horses behave well; it is in the subsequent "hitchings up" that vice apears. It is perhaps due partially to breeding, but in most cases it is due to the horse resenting to be worked with a shoulder that still feels the effect of his first attempt at pulling. It is he horse's only way of telling his driver that there is something wrong and that it hurts to pull. It is a serious matter in horse training to let a horse know that he cannot be made to pull, and nine cases of balking out of every ten are due to some ill-fitting adjustment. Overloading is a common error in horse breaking, but an empty wagon is an overload to a horse with sore shoulders, and balking is the lesson he learns from the experience.

It is the best class, the keen spirited thinking horse, that is taught the balking vice through ill fitting harness. A dullard horse may pull through with open sores and raw flesh next to the collar pad, but it is inhuman and reduces his value and utility. The fault of balking is generally blamed on the horse when it invariably is the lack of sympathy and consideration in the teamster. A slight soreness or bruising, that cannot be quickly detected, is enough to keep a keen spirited horse from doing his best, and it is the teamster's duty to be on the outlook for the first signs of resentment on the part of he horse, and rearrange the collar or any misfit in harness. No teamster should, at breaking in time or at any time, use horses as if they were inanimate and void of feeling.

With the firm collar that has no top fastening, and has to be put on over the head, a soft pad, made the shape of he collar at the neck top is the best arrangement when spring and summer work reduces the size and changes the shape of the neck. With a collar that fits the neck and a shoe that fits the hoof, every horse that is hitched up to work will express his gratitude in efficient work and increase the returns to the horse breeding industry by thousands of dollars.

Sweat pads are of no value to the utility of the horse and many times add only to his discomfort. A well-fitting collar requires no sweat pad, and to an ill-fitting one it only magnifies the trouble. Everyday at noon in warm weather the collar should be taken off, and set up to dry—face towards the sunshine—for a few minutes and when dry cleaned with curry comb and brush. Grooming the collar's facings is of equal importance to grooming the horse. If the collar is not kept clean, grooming the shoulder is at a discount in shoulder keeping. When the horse comes from work hot and sweating the shoulders should be bathed with cold water, in which there has been mixed a little common salt. No salt must, however, be used where there is a wound or broken skin. No work horse should have broken or bruised shoulder skin, and the teamster that allows the horse under his charge to become so affected, is not worth his salt to his employer, and is a blot on the hall mark of the horse breeding industry.

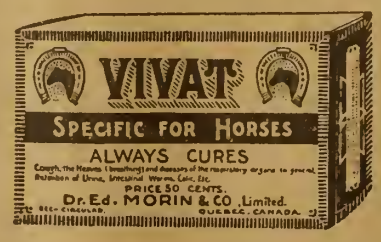
The Recognized Specific of Diseases of the Horse



A sovereign remedy in powder form which cures, Coughs, Heaves, Colic, etc. It strengthens the work horse as well as the race horse, and enables them to do more and better work. It has been successfully prescribed by many veterinarians notably by Dr. J. D. Duchene, in many critical cases, where results have proved remarkable.

A 50c box will be sufficient for six days' treatment.

DR. ED. MORIN & CO., LIMITED, - - Quebec, Canada

days she could travel like a greyhound, but let her get too much hay or on a foggy day and she had heaves just fifty times worse than any horse livin'. And afraid of autos—the first one we met she reared and snorted, fell down, frothed at the mouth, bled at the nose and stiffened out on the ground like a dead horse, with the harness and shafts tangled about her so we had to cut part of the straps to get her loose. After a bit she came to and as soon as we got her hitched another auto dashed by and down she went again. I couldn't quit peddlin' milk to devote all my time to brinin' her to so I says: "Here goes. Somebody's goin' to get her."

I took her over to Mike Anderson's one afternoos when the weather was just right and she hadn't had any hay for two days. I managed to get her over safe by goin' across fields and coverin' her head with my coat when an auto tooted about three-quarters of a mile away. You know Anderson was a tricky, hoss-tradin' cuss and I says to myself: "Here's where Anderson gets his if he opens his mouth at all."

"What's the matter with her?" says Anderson.

"'Fraid of autos," says I. "She lunges and jumps when she sees an automobile, but she soon gets quiet."

"I've got a good pony to trade you," says Anderson, leadin' out a bald-faced broncho with brands all over him. After awhile Anderson said if I'd give him $10 to boot it would be a trade. I thought it would cost me about $10 to bury the mare if I didn't trade her to Mike so I might as well give it to Mike, so we traded.

That bronk wouldn't move an inch hitched up, you couldn't even get him to walk down hill with anything that looked like harness on him and he had cost me $45, besides I'd killed a lot o' time foolin' with him and the mare. "Somebody'5s goin' to get him, too," says I. I took him to the horse sale and didn't get a bid on him. I tied him out to the rack, stood by him and asked everybody that passed if they wanted to buy a saddle pony.

"What dye want for him?" they'd say. "Twenty-five dollars," says I, and they'd keep agoin'. "Then give me five dolars and you can have him," I'd yell after them, but nobody turned back.

Finally Mike Anderson came along and says, "How are you gettin' along with the pony?" "About as well as you are with the mare I'll bet," says I. "What did you do with the mare anyhow, Mike?" "Well," says Mike, "she throwed a fit when she saw an auto, floundered around, and dropped like a dead horse and after layin' there awhile, I decided that since you'd made me a present of her and paid me for takin' her besides, we'd just shoot her and sell her pelt, so we drug her over into th field." "That's good," says I. "Now give me $5 for the pony and you can have him back." "All right," said Mike and counted out the money.

"That reminds me," said the other milk man, "when I was a boy I had a cousin, who started out with a good horse, made three trades and came back afoot and out $20 besides."

FOALS NEED SPECIAL

The 70 days between July 1 and Sept. 10 will, in many cases, determine the condition for the next 10 months of foals now suckling their dams. The well-bred foal, be it mule, light or draft foal, must have good care if it is to develop as its parentage warrants. Never was the difference in value between the good foal and the inferior one greater than at present. It is possible that it will not pay to feed grain to the foal from inferior parents which promises at best to become nothing more than a cheap, nondescript horse.

The supply of mothers milk which foals have had since birth, together with good pasture and reasonably cool spring weather, have kept most of them in good condition up to the present. But the extremely hot weather and flies of summer, the dry and usually scarce pasture of July and August, and the hard work done by the mares, all work hardships on nursing foals, if they are not protected against these conditions.

Spring foals will learn to eat grain readily if given a chance, and it is profitabel with good foals to arrange so that they can have access to clean, fresh grain. A satisfactory mixture consists of 2 parts crushed corn, 2 parts crushed oats and 1 part bran. If crushed grain is not available, shelled corn and shelled oats may be used.

If foals' mothers are being used for warm work, the foals should not be allowed to follow them, but should run together in a roomy, clean, well-ventilated box stall or paddock. If a small pasture, surrounded by a good fence and containing shade, is available, it makes a fine place for foals. Fresh water should be available constantly, if possible, or else it should be supplied often.

Foals soon become accustomed to staying in a paddock, nursing morning, noon and night, and running with their dams during the night. Handled in this way, foals will go through the trying time of summer in better shape than those treated otherwise. They can be weaned without difficulty and without a setback; and after weaning time, pasture will again be better, the weather will be cooler, and they will o into winter quarters in a satisfactory condition.

With the present short supply of good horses, it seems advisable that attention be concentrated upon the foals which promise to develop into good horses, even at the sacrifice of the less valuable ones.

SCRATCHES OR MUD FEVER

Scratches, mud fever and cracked heels in horses all arise from the same cause. In cracked heels we have slight swelling and a tenderness in the hollow of the heel, and the skin at this part cracks, and if neglected will often become inflamed so badly that they will throw off a discharge. In most cases they toughen the skin at the edges of the heels, caused by the crusting of the discharge thrown out.

The cause of cracked heels in horses is most often found in the animal being worked or made stand in mud or manure, or anything that irritates the heels, without proper attention being given to the cleaning off or wiping off the irritating substance. Improper circulation and imperfect nourishment and several other constitutional disorders tend to bring about cracked heels, and the skin of many horses is sensitive at this part, causing hard or fast work to open the heels.

The treatment is directed to first removing the cause, if possible, and if the animal has to stand in deep mud or worked in any irritating soil, the legs should always be carefully dried off and cleaned daily. A bran mash should be substituted once or twice a week for the regular grain ration, and a physic ball of aloes is useful to clean out the digestive tract and assist in helping the circulation. Fowler's Solution of Arsenic, a tablespoonful in the feed for about 10 days, should be given, and a local treatment of Zinc Oxide Ointment and Lanelin, mixed together, may be applied to the heels. A useful stable lotion that is used by many trainers or race horses, and that has been recommended by the writer, is made by mixing one-half ounce of sulphate of zinc, one ounce of sugar of lead in a quart of water. This lotion is useful in all conditions where the skin of the horse has become cracked.

Grease or Canker of the Heels

Grease of the heels, or what is commonly called "grapes," is an inflammation of the heels, and often extends up toward the hock or knees and gets the name grapes from the growths that are formed, resembling clusters of grapes. Usually in the early stages an oozing of serious matter is noticed and the heels are swollen, and as the swelling extends up toward the hock or knee, the exudate thrown off becomes cloudy, with an odor, and the hairs stand erect on this part of the legs. The foot may become involved and the frog gives off a fetid discharge and teh horn becomes soft and whitish in color. The treatment consists in having clean and hygienic surroundings, and the animal should not be allowed to stand in muddy earth or in any substance that will cause to irritate the legs. The stable lotion that has been mentioned for cracked heels is useful as a local application, and the grapes may be rubbed daily with lunar caustic or some other caustic to destroy them. Dressings of carbolic acid should be applied to the hoof if it is affected, and a physic ball of aloes should be given at intervals.—By Dr. E. F. Hannan, V. S.

Bots in the horse's stomach are hatched from the yellow eggs which are laid by nit flies on horses' legs and on their throats. If the animal is permitted to lick itself, some of the eggs or the young maggots are carried to the mouth and they later reach the stomach, where they attach themselves and feed on the food consumed by the animal. The eggs can be destroyed before the animal licks them off by rubbing the hairs bearing the eggs lightly with a rag moistened with coal oil.

Horsemen Attention !

Dr. J. Woodbury's Horse Liniment and Dr. J. Woodbury's Condition Powders will save and preserve the life of your horses. Their use will cure and prevent the disease common to horses, such as Cough, Colds, Distemper, Spavins, Pinkeye, Splints, Curbs, Enlargements, Cracked Hoof, Kidney Trouble, Fevers, Cuts, Sores and will remove bunches of all kinds.

BEFORE USING

Why have a sick or lame horse, when you can get a reliable and warranted remedy? The leading horsement of the Dominion endorse Dr. J. Woodbury's Horse Liniment.

FOR SALE ALL DEALERS

PRICE 25 CENTS

Do you know that "Dr. J. Woodbury's Horse Liniment" is endorsed by all the leading horsemen of the Dominion. Save and preserve the life of your horses by its use. It will cure and prevent disease common among horses.

DEMAND
DR. J. WOODBURY'S
HORSE LINIMENT

AFTER USING

Use this preparation thoroughly for all and every disease of the horse for which it is recommended. Criticise it closely. Carefully watch, mark and notice, its effects, and, honestly judging it on its merits, you will be compelled to endorse it.

POULTRY.

HANDLING POULTRY FLOCK WHEN TUBERCULOSIS ABOUNDS

Tuberculosis causes greater losses than any other disease of poultry. Formerly it was not believed to be of much importance to the poultryman. No it is known to exist in many sections of the country.

The cause of tuberculosis in poultry is an extremely small bacterium or germ, the tubercle bacillus, which closely resembles the germ responsible for tuberculosis in man, cattle, and hogs. This organism is so small that it can be seen only with the aid of a high power microscope.

The germs cannot grow outside the body, but once they become implanted in the body, they multiply rapidly, causing the formation of small nodules or tubercles; hence the name tuberculosis, says a Wisconsin circular.

Symptoms Shown by Diseased Fowls.

Here are the symptoms most often seen in tubercular fowls:

In the majority of cases, lameness is the first and may be the only symptom, the affected birds otherwise appearing perfectly healthy. In some cases, limping is seen only after the disease is well advanced. If the joints are affected, they usually swell and are painful. When these symptoms are seen, they should not be attributed to rheumatism, as is frequently done.

In advanced stages the feathers become ruffled and the bird has a droopy or unthrifty appearance. The general lack of condition is shown by paleness of the comb, wattles and skin.

There is a gradual loss of flesh until the diseased fowl becomes mere skin and bones. In marked cases practically all the breast flesh disappears. The term "going light" is then often applied. The appetite is usually good but little benefit comes from the food consumed, showing that the processes of digestion, absorption, and nutrition are interrupted.

Sometimes no symptoms are evident until the disease has reached an advanced stage. Usually birds under one year of age do not show recognizable symptoms as tuberculosis is a slowly developing disease and does not cause death until after a year or more. The length of time between the appearance of the first symptoms and death varies with the resistance of the birds and the care given them. Ordinarily this will be several weeks and many be much longer.

Ways by which the Disease is Introduced.

Tuberculosis is most commonly introduced by birds purchased from flocks in which the disease exists. Another way by which it is brought into the flock is through the eggs from infected hens. Still another way is through meat scraps and green bone which contain poultry offal, and kitchen garbage containing the entrails of market poultry.

Methods by which the disease is spread

Fowls that have advanced tuberculosis throw off the germs with their excreta, scattering them widely. The poultry yards and house and the drinking and feeding paces thus become contaminated and afford the greatest chance for the infection of other fowls. Feeding the entrails from poultry dressed for market is a method of spreading tuberculosis and other diseases in healthy flocks. For this reason the poultryman should never throw the entrails into the pens, unless they have been cooked and should not allow dead birds to lie there, even for a short time.

Experimentally, hogs have been given tuberculosis by feeding them carcasses of tubercular poultry. Under ordinary farm conditions hogs have contracted the disease from infected poultry. So far as is known, no human being has ever contracted the avian form of tuberculosis. Furthermore, under natural conditions, fowls never contract tuberculosis from other domestic animals or from man, even by cating material containing immense numbers of tubercle bacilli.

It is certain that tubercular hens are dangerous to keep on the farm, for they certainly will communicate the disease to healthy hens with which they may come in contact, and may be a means of infecting hogs.

How to recognize Tuberculosis.

While all the symptoms of tuberculosis may be seen in one bird, it is rare to find them. Lameness is most commonly seen and should always be viewed with suspicion. Some diseased fowls will fail to show noticeable symptoms and die without having attracted the attention of the caretaker. Furthermore, the character of the symptoms is so indefinite that they cannot be relied upon with any degree of certainty. Therefore, to determine whether tuberculosis exists in a flock, it will be necessary to examine the carcass of a fowl which has died, or to kill a sick fowl and make a careful post-mortem examination for lesions of the disease.

Lesions are the changes which occur in the tissues as a result of the disease. In tuberculosis they start as whitish or yellowish pin-head-like nodules or spots which form either on the surface or organs, or are imbedded deeply in the sofe tissues. Slowly or rapidly, depending on the resistance of the fowl, these nodules grow until in advanced cases they become as peas, or even larger.

Any organ in the body may show the lesions of tuberculosis. The organs most frequently involved are the liver, spleen, and intestines. In fowls the lungs are less often affected than in cattle, hogs, and man.

The liver often enlarges to several times its normal size and appears spotted because of the large number of nodules or tubercles it contains. The liver is more often affected than any other organ because it acts as a filter for all the bood from the bowels and catches in its meshes any germs of tuberculosis that may be absorbed.

The spleen, when diseased, becomes firmer and much larger, and shows the characteristic tubercular nodules which extend deeply into it.

The intestines show tuberculosis by developing nodules of varying sizes at different places. When a spotted liver or spleen is seen, or intestines with tubercles are found, there is a decided probability that tuberculosis exists. However, there are certain other diseases of poultry in which similar lesions occur, but in these the surface of the organs is not studded with the peculiar raised nodules which, by cross sectioning, are found to extend deeply.

To be absolutely certain about the diagnosis, it will be necessary to have a microscopic examination made of the cheesy material in a tubercle to see whether tubercle bacilli are present. In tuberculosis of poultry the bacilli will be found in almost unbelievable numbers, a condition quite different from that of bovine tuberculosis, where it is often difficult or impossible to find any.

The Tuberculin Test.

Recently a modification of the tuberculin test, which is used so generally for the diagnosis of tuberculosis in cattle, has been adapted for testing fowls. It consists in the injection of a special fluid (tuberculin) into the wattle. Twenty-five hundredths cubic centimeters of tuberculin prepared from the avian type of the tuberculosis germ is injected with a very fine hypodermic needle just beneath the outer skin of the wattle, making an enlargement about the shape and size of a pea.

If the bird is tubercular, one or both wattles will swell in 12 to 18 hours from two to twenty times the normal size. Birds in advanced stages often fail to react, but if some members of a flock react to the test, those in the advanced stage can be discovered by their extreme loss in weight.

Handling Infected Flocks.

Medical treatment is useless, so other means must be sought to control the disease. Moreover, the trouble and expense to treat individual birds would not be justified.

Valuable breeding stock, if not infected, may be saved by having a veterinarian apply the tuberculin test to discoxer the diseased birds. These must be removed at once to stop the progress of tuberculosis in the flock.

Because tuberculosis is very slow in its developments, that is, runs a chronic or long drawn out course, the disease is difficult to handle once it gets a foothold in a flock.

In case tuberculosis is discovered in the farm flock experience has shown that the quickest way to get rid of the disease is to dispose of the entire flock at once. Fowls that are in good condition may be dressed for food. Judgment as to the fitness of the carcass for food would depend on its condition and on inspection of the internal organs hen they are removed.

If a poultry house is dark and damp, windows to admit an abundance of sunlight should be provided. The direct rays of the sun are very effective destroyers of tubercle bacilli. It will be best to delay placing other poultry on the premises for six months or longer. The place must be cleaned and disinfected before restocked with poultry.

It is possible to hold the disease in check by the following method, but it is not recommended as very practicable for some affected fowls may be left: Kill all lame and very light hens; dispose of all hens when they reach two years of age; provide new yards and a temporary house at some distance from the old in which to start another flock from healthy stock.

Ridding the Premises of Tuberculosis

By following step by step these practical directions, the poultry houses and yards may be effectively rid of tuberculosis and other diseases caused by germs:

1. Collect for fertilizer all droppings and litter in the houses.

2. Scrape the floors, walls, and ceiling thoroughly, being careful to scrape out all corners so that no dust or dirt remains.

3. Remove and clean out all hoppers, drinking fountains, nests, and roosts.

4. Saturate everything in poultry houses and yard with a reliable commercial coal tar disinfectant, prepared according to the directions of the manufacturer as given on the original package, being sure that the spray mixture reaches all corners, cracks, and crevices.

5. Repeat the application of disinfectant after ten days.

6. Board up all spaces under hogpens, corn-cribs or other outbuildings where the hens might stray.

7. Fill with fresh dirt all sink-holes and wallows.

8. Plow and crop, when possible, all places where chickens have been allowed to run.

THE COST FEED OF A PULLET

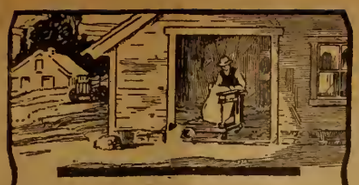
(By Leslie E. Card)

The question of how much it costs to produce a pullet is one of considerable importance to every poultryman, whether he is raising fifty chicks or 5,000. It is especially important because the problem is one of annual occurrence, owing to the necessity of renewing part of the flock each year.

A series of experiments started at the Storrs, Connecticut, Experiment Station in the spring of 1915 was designed to establish what might be called normal growth curves for Rhode Island Reds and White Leghorns.

Incidentally, the data collected show the amount of feed required to grow a pullet of either of these breeds to laying age, and the number of pounds of feed consumed for each pound of meat produced at different ages.

The method of conducting each experiment was to incubate enough eggs to bring off a hatch of 300 strong chicks. No weak or puny chicks were placed in the brooders. A policy of rigid culling was followed throughout the progress of the experiment, the purpose being to handle the flock just



Handy Scales for Farm Use

Convenience and service are the chief features of the

Fairbanks Farm Scales

The handle at the base of the weighing post permits of ready transportation on its own wheels to any part of the farm buildings. In house or barn or dairy it serves any purpose up to 2000 pounds capacity.

Fairbanks Portable Farm Scales are compact and absolutely accurate. The platform is 34 x 25½ inches and has a clearance of 11 3-8 inches above the ground.

Write our nearest branch for full details of this and other types of scales.

as it would be handled under good commercial management.

The feeding practice was in accord with the method which has been advocated by the station for several years. No solid feed was given until from thirty-six to forty-eight hours after hatching. Sour milk was the first feed and was kept constantly available until the birds were fourteen weeks old. The first day's ration consisted of fine chick scratch feed in which had been mixed a generous amount of grit. As soon as thec hicks learend to eat it well this mixture was fed in litter so as to insure plenty of exercise. Dry mash was hopper fed after the first week and was constantly available.

Leghorn cockerels were segregated at eight weeks of age, while in the case of Rhode Island Reds sesparation of the sexes was made four weeks later when the birds were three months old. After eight weeks in the case of Leghorns, or after twelve weeks of age with the R. I. Reds, the data refer only to pullets. Chicks were reared on the colony plan and were brooded under coal-stove hovers. Throughout the summer, until ready to go into the laying houses, they were kept on free range.

Young Birds Grow Fast

The chicks were weighed just before being placed in the brooder and at seven-day intervals thereafter. Weighings were made between 5 and 6 a. m. disturb the chicks as little as possible and so that their crops should be entirely empty at weighing without the necessity of withholding feed beyond the regular feeding time.

Weekly records were kept of the amount of grain, mash and milk consumed. In all calculations of feed consumption milk has been estimated at ten per cent. solids and has been added to the grain and mash on this basis.

It is a well-established fact that growing pigs make the cheapest gains in weight while young. According to Dietrich, it takes about four months for a pig to grow his first hundred pounds. He will consume during this time 240 pounds of feed. To grow the second 100 pounds takes only two months but 300 pounds of feed. The third 100 pounds takes three months anad 630 pounds of feed: while the fourth 100 pounds requires nine months and about a ton of very good feed.

The data collected at the Storrs Station seem to indicate that a very similar condition exists with chickens. The following table gives average figures for Rhode Island Reds:

	Pounds of Growth				
	1st	2nd	3rd	4th	5th
Number of weeks to make each lb.	6.5	3.5	5.5	5.5	10.0
Pounds of feed for each pound gain	3.0	3.2	6.5	10.0	18.0

It is very evident that the fifth pound is a costly addition as compared to the second or third pound. Consider for a moment a flock of Red pullets averaging three pounds each. To put them up to five pounds each will cost at least a dollar a pullet for feed alone, assuming that feed can be bought for four cents a pound.

Big Birds Need Most Feed

The next table shows the same data for Leghorns. Very few Leghorns reach four pounds in weight and for this reason the figures are given only to three and a half pounds. The Leghorns show up better in this comparison because they do not have so long to grow:

	Pounds of Growth			
	1st	2nd	3rd	Next Half
Number of weeks to make each pound	7.5	5.5	6.0	4.0
Pounds of feed for each lb. of gain	3.2	4.5	7.0	5.0

Table 3 shows the number of pounds of feed consumed for each pound of gain made in successive eight-week periods, and the cost when figured at four cents a pound of feed. Figures for the fourth period are omitted in the case of Leghorns, as this would extend beyond the period of ordinary growth.

Period	R. I. Reds		Leghorns	
	Feed per		Feed per	
Weeks	Lb. Gain	Cost	Lb. Gain	Cost
1- 8	3.5	$0.14	3.5	$0.14
9-16	5.5	.22	6.5	.25
17-24	8.0	.32	10.0	.40
25-32	23.3	.93	...	...

The last table shows the average amount of feed consumed a week by each ten chicks at several different periods in their development. Notice that the Reds keep in advacne of the Leghorns from the very first:

Feed Consumed per 10 Chicks

Weeks	R. I. Reds lbs.	Leghorns lbs.
1	1¼	1
8	10	8
16	15	12
24	15	15
32	18	16

To grow a R. I. Red pullet to twenty-four weeks of age requires about twenty-four pounds of feed. To grow a Leghorn pullet to the same age takes about twenty pounds. After that age the consumption is from one and a half to 2 pounds to each bird in a week When there is added to the feed cost the cost of hatching eggs, incubation, coal for brooding, use of equipment and labor, it is readily seen that the growing of pullets is a rather expensive proposition. Because the cost for feed increases so rapidly as the birds grow older it is important that the young stock should have the very best of care and an abundance of feed to obtain maximum growth during the time they are putting on flesh most efficiently.

CRATE FEEDING

What is it?—It is enclosing birds in small coops or craates for the last few weeks' finishing before killing for market.

What advantages has the method?—

PEERLESS PERFECTION
applies to our Poultry Fencing just right. It keeps your chickens at home—and their enemies out. Each intersection securely locked—the kind that stays "put."
Peerless Poultry Fence
is made of the best Open Hearth steel fence wire—tough, elastic and springy—and will not snap or break under sudden shocks or quick atmospheric changes. Our method of galvanizing prevents rust and will not flake, peel or chip off. The joints are securely held with the "Peerless Lock," which will withstand all sudden shocks and strains, yet Peerless Poultry Fence can be erected on the most hilly and uneven ground without buckling, snapping or kinking. The heavy stay wires we use prevent sagging and require only about half as many posts as other fences. We also build Farm and Ornamental Fencing and gates. Write for catalog. AGENTS NEARLY EVERYWHERE. LIVE AGENTS WANTED IN UNASSIGNED TERRITORY.
THE BANWELL-HOXIE WIRE FENCE CO., Ltd., Winnipeg, Man., Hamilton, Ont.

It keeps the birds quiet and under control. No flesh is wasted or muscles hardened by undue exercise. The added flesh during this finishing process is the cheapest of the whole bird to produce and it increases the value of the whole carcass from 10 to 25 per cent.

How is the crate made?—Almost any packing box will answer for a temporary crate, but it is better to make a good one that will last. The crates in general use are six feet long by sixteen inches wide by twenty inches high and divided into three compartments. They are made of laths or slats, nailed on a light frame.

What kind of a bird?—The flesh of any bird is improved by finishing in the crate. Best results are obtained from cockerels of the general purpose and heavy breeds.

What is the best feed?—Finely ground grains mixed with milk, make the best ration. Oats, barley, corn and buckwheat are all good. Two or three grains mixed together are better than one alone. Wild buckwheat screenings also make a cheap and satisfactory feed. Milk, preferably sour, or buttermilk, is very valuable for mixing the feed.

Other things to remember.—Do not feed the birds for twenty-four hours after putting them in the crate and then feed very sparingly for several days. Keep the birds hungry for two or three days and gradually increase until a full feed is given, then feed twice a day just what they will eat up clean. Clean out any feed left in the trough after each meal. Dust the birds for lice before starting and again before killing. Kill by bleeding in the mouth and piercing the brain. Pluck, dry and cool before packing. Write Experimental Farm for Bulletin No. 88, for further information.—F. C. Elford, Dominion Poultry Husbandman.

TO MAKE PROFIT FROM YOUR POULTRY BETTER STOP LEAKS

My observation teaches me that many a farmer considers the farm flock a sort of necessary nuisance. He feels that it is beneath his dignity and a waste of time for him to give any help in chicken raising. Still under favorable conditions, nothing on the average farm pays better for the time and money invested.

It is hard for the farmer to realize that, because the egg checks look so small and insignficant beside the hog checks which spring and fall run into three figures, there is no comparison in value of the "porker" and his feathered friend.

Let him not forget that the egg check comes every week and although he may not be able to add to his bank account every time a check comes, that same bank account looks more prosperous than if it were drawn on every time the family was in need of groceries or every-day clothes. It has been my experience, too, that the hen did her part toward buying the Sunday clothes and even gasoline for the automobile. All this she has done besides furnishing fresh eggs for the table the year round which fact helped along the farmer's hogcheck to say nothing of the chicken roasts, stews and fries which saved the pork and thereby increased the hog check.

So much for what the chickens do for the farmer. What does the farmer do for the chickens? Oftentimes he does not do nearly so much as he should or as he could to make them more comfortable and as a result more profitable.

In the first place the farmer seldom houses his flock properly. Often in winter the quarters are subject to draughts and snow sifts through the cracks and broken window panes. Then during the summer farm folks find so many things to do of seeming more importance than the poultry, consequently they are nelected. They do not get their feed regularly, if at all, and their houses become infected with lice and mites, and so the farmer begins to wonder why the hens quit laying so early.

Hens will lay in the spring even under adverse conditions, because it is their nature, but as summer advances they must have some atention and care if they do not fall off in egg production. Another cause of loss and disappointment with the farm flock is the fact that too often both young and old stock are given the same runs year after year without any means of renovation being employed, until the soil becomes foul and contaminated and a fruitful source of disease. A frequent sprinkling of lime is good but the runs should be occasionally plowed and seeded.

Another thing I have learned from observation has been at close range for I have lived on a large farm where poultry keeping was a side line and often not so profitable as it should have been. This last mistake which I shall mention is one of feeding mature and growing stock together. In the first place it is a case of the "survival of the fittest," the stronger thriving at the expense of the weaker. Also it is a mistake from the fact that mature and growing stock require a different kind of feed.

I have here ctied a few of the "leaks" which seem to me to be most prevalent among the poultry keepers. Perhaps if you investigate you will find yours in a different direction at any rate if you the dissatisfied with the returns from your flock it will pay you to investigate.—G. A. Meredith.

7% With Safety

We can offer investors a well-secured 7 per cent. Mortgage Debenture Stock. The issue—$2,000,000—is secured by a mortgage on assets, valued at $15,000,000, of a large Canadian pulp and paper company. Present net earnings are more than four times the interest requirements. A new mill, now nearly completed, will increase the company's earnings.

Investors in this Mortgage Debenture Stock share in the surplus earnings of the company with the development of business. Your savings could not be more profitably invested with safety, so that you cannot do better than write at once for further information. Address

AN OUNCE OF LOYALTY

(By R. N. Wall in Everybody's Magazine.)

The placid calm of a late September afternoon pervaded the dim old walnut-furnished office of the Mears Plow Works. Spider webs fell in festoons over the tattered backs of fat ledgers and spare journals stacked upon the shelves. Dust lay heavy upon yellow packages of letters and contracts stuffed into rows of pigeon holes below the books.

Burk, the narrow bookkeeper, was noiselessly matching nickels with his assistant. The invoice-and-order clerk had his head bent over a sheet of figures so placed that it permitted his eyes to fall upon the open pages of "Treasure Island." The sleepy stenographer was nodding over a bit of fancy work, and Tommy, the solemn office boy, was doing nothing whatever.

Within the private office the same drowsy atmosphere prevailed. The young president, John Mears, was at his desk, the sleeves of his custom-made shirt rolled up like any workingman's; but he was not working much. Opposite him, Elizabeth Carter, the trim young woman who acted as office manager, now and then raised a hand to her pretty mouth to stifle a yawn.

Into this backwater of business plunged a brisk young man, as suddenly as a gasoline launch bursts into a peaceful millpond. He was a slender person, with big hornrimmed eyeglasses astride a prominent nose, and low shoes with extension rubber soles. He entered with such purposeful swiftness that the somnolent office force scarcely perceived him until he had thrust his card at the president.

Mears rose with outstretched hand. "I'm mighty glad to see you," he genially greeted the visitor. "Miss Carter this is Mr. Epperson, the efficinecy expert with whom we have been corresponding, and who is going to show us how to make two plow points spring where one sprang before. Miss Carter is a stockholder," Mears explained to Eperson, "and has charge of our office; she used to be my father's assistant. Now she's mine, or I'm her's—I hardly know which. I've been in charge only the few months since my father's death, and Miss Carter really knows more about the business than I do."

Miss Carter gave the expert a firm, cool hand and an appraising glance from her wide, clear eyes She was not a beautiful woman, but she was so clean and fragrant and wholesome that she was charming.

"Mr. Mears thinks that our ways are old-fashioned and that we need outside assistance," she said. "I believe you installed a system at the North Bend Chilled Plow Works. Do you think a little business such as ours needs a system like the great plow works there?"

"More," declared Mr. Epperson bluntly, with a suggestive look towards the open door, "if your whole works are run like your office."

Miss Carter looked at the young man in cold surprise. For an instant she forgot that he was engaged to criticize.

Mears broke in quickly: "That's just the trouble! I can run a football team, but I can't get this place on its toes "

He was a very splendid young president, tall, wide-shouldered, narrow-hipped, with clothes that seemed a part of him. The third of a line of famous plow-makers, his own business experience had just begun. His father had died while John was still at college, and he had been shot into the business with a suddenness from which his head was still swimming. With the ardor of youth, he burned to put the conservative old plow company in the front rank of modern trade.

He placed a perfectly kept hand on one of the pearl push-buttons lately installed upon his father's old desk.

"Tommy," Mears instrutced the solemn office boy, "ask Mr. Moran to come in. Moran is our superintendent," he informed Epperson. "He's a fine fellow but getting pretty well along in years, and I can't hurry him out of his usual routine. Perhaps you can."

"That's my business," asserted the expert. His prominent light blue eyes roved about, absorbing every detail.

A heavy step made the worn floorboards of the outer office creak, and Dan Moran rolled in. He was a bull-necked old giant of a man, with a great, ruddy, good-natured face. His iron-grey hair had been hastily wet and plastered on his skull, and as he advanced he wriggled his wrinkled red neck in a blue linen collar buttoned upon a blue flannel shirt. His big jaws were busy with a mouthful of fine-cut.

"You wanted to see me, Johnny?" he inquired, and ducked his head in comprehensive greeting. He had carried the president pick-a-back about the foundry when Johnny was four.

'.I want you to meet Mr. Epperson, an efficiency engineer, whom I have engaged to make a survey of the shops."

"How-de-do?" grunted the old man, giving the expert a sharp look from under his shaggy, grizzled brows.

"You know, Dan," Mears went on, fingering the black opal pin that studded his rich scarf, "that things here aren't run the way I think they ought to be. We've got too much capital tied up in dead stock and past due accounts; our output is small in proportion to our force; much of our machinery is scrap; we've got some old fogies for foremen——"

"Hold on, Johnny; lemme see if I git you right," interposed Moran goodnaturedly. He pulled a chair in range of the cuspidor, sat down, and spat. "You mean you don't like the way I'm running the works?"

"Not exactly that, Dan," said Mears, with a little frown at Moran's bluntness. "My criticism is of the whole business—office and factory."

"I dunno a darn thing about the office, but I kin tell you this, Johnny: the shops is all right. I helped your granddaddy start this business. Him and me laid out this plant and hired the men; a lot of 'em are here yet—"

"I presume that's one trouble," interjected Epperson. "Old concerns have a tendency to accumulate dead wood."

"There ain't no dead wood around here, young man," snorted Moran. "Maybe some of the boys ain't as spry in the legs as they was once, but their heads are working!"

"The point is that we aren't paying dividends," exclaimed Mears impatiently. "You can talk a week and you can't get around that."

"We're going to pay 'em," Moran insisted mildly. "I'm just as anxious for dividends as you are. Ain't I got forty shares of stock?"

"We can't declare any until we have a surplus, and you know how cramped we are for ready money."

"Wait until the new line of chilled plows we're building gets started. You know it's cost us a heap of money for patterns and material, Johnny."

"That may help, but I want to know how we stand," Mears insisted. "Mr. Epperson is here to examine impartially and report to me; then I'll know what to do. I realize that I lack the necessary experience to assemble the data myself."

"That would come, Mr. Mears," Miss Carter ventured.

"Pardon me," cut in Epperson, turning his horn-rimmed gaze upon her. "You are wrong. A man is too close to his own business to get the proper perspective."

"In any case," John spoke firmly, as he rose and turned down the sleeves of his crisp and costly shirt. "Mr. Epperson is here. I want the survey made, and I expect both you and Miss Carter, Dan, to give him every assistance."

"Sure we will," agreed Moran heartily. Miss Carter said nothing whatever.

She had her say, however, when the young president had left with Epperson to see that he found comfortable quarters.

"I don't approve of this thing a bit!" she declared, her attractive face flushed. "Mr. Mears is so impulsive!"

"Johnny's all right," said the old superintendent. "He's like all boys—he wants to move the world in a minute. Let this here expert experiment."

"We've always been like a big family," objected Miss Carter. "Most of our men have been here a long time; they're well paid and considerately treated, and they feel that they belong. I hate to see that sentiment spoiled."

"I reckon we'll have to shut our eyes and gulp our medicine," opined Moran in his easy-going way."

"You can if you like," retorted the fiery young woman, "but Mr. Epperson will have to do his experimenting without and help from me. I've been here five years, and John Mears hasn't been here five months'"

"And I've been here forty," grinned Moran, "and learned not to fly off the handle. Go slow, young lady," he warned, as he shambled off towards the factory.

Miss Carter entered the office next morning, cool and trim in summer white. She was a little earlier than usual, for she had planned to finish her routine work before Epperson arrived.

Instead she found that efficient gentleman already on the job. He was standing over the stenogarpher, a watch in one hand, a perfectly pointed pencil in the other, his note-book open on the desk before him. Pink and moist, the girl was hammering madly upon her machine, frequently stopping to make frenzied corrections. Burk was sulkily posting; the other clerks were desperately busy, and, in the president's office Tommy was raising a perfect whirlwind of dust.

"Good morning, Miss Carter," said the efficiency expert curtly. "I expected that you or Mr. Mears would be here to introduce me to your staff. As you were not, I have taken the liberty of becoming my own sponsor."

"That is all right," answered Miss Carter, annoyed, but determined not to show it, "I meant to get here early. Mr. Mears seldom comes in before ten."

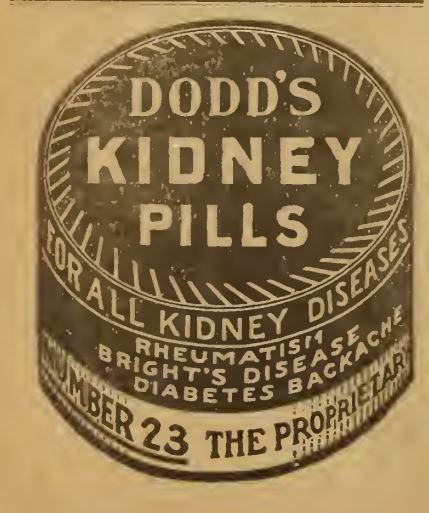
Mr. Epperson raised his thin brows.

For two hours Mr. Eperson delved into the office methods and expounded his theories. He overlooked nothing, and very little met his approval. Miss Carter kept her composure, but it was a strain. As for Burk, he found opportunity to whisper:

"Say, can't we get this guy out in the factory and shove him against a band saw?"

About ten o'clock Mears strolled gracefully in. "Well, old man," he greeted the expert genially, "what do you find wrong with our little old office?"

"Pretty much everything." Epperson looker his disgust. "I'll give you the details in my report. I'll take the factory now."



ACADIA UNIVERSITY
WOLFVILLE - - Nova Scotia.

Departments
Arts and Sciences. Applied Science. Theology.
Degrees
B.A., B.Sc., B.Th., M.A., and certificates admitting to the best technical schools. First two years in Agriculture given as electives in B.Sc. course. First year in Medicine, Law, and Theology given as electives in B.A. course.
Special Courses
Courses in Surveying, Draughting, Shopwork, Chemistry, Electricity, and Bacteriology, for returned soldiers and men anticipating military service.
Equipment
Largest undergraduate faculty in the Maritime Provinces. Three new and splendidly equipped Science Buildings.
Expenses
Expenses light, and over $1,000.00 given in prizes and scholarships yearly. Send for calendar to
Rev. GEORGE B. CUTTEN, Ph.D., D.D., LL.D., President.
Next term begins Oct. 2nd, 1918.

ACADIA LADIES' SEMINARY
WOLFVILLE - - Nova Scotia.
The Aim. — To prepare Girls and Young Women for Complete Living.
The Courses.—Twelve; including College Matriculation, General, Music, Art, Expression, Household Science, Business.
The Faculty.—Twenty-four Teachers of fine personality and Special Training.
The Equipment.—Modern and First Class in every respect.
A Junior School.—For Younger Pupils.
Information.—Write for illustrated book to
Rev. H. T. DeWOLFE, D.D., Principal.
Next term begins Sept. 4th, 1918

Acadia Collegiate and Business Academy
WOLFVILLE - - Nova Scotia.
A Residential School for Boys and Young Men.
Ninetieth Year
Courses. — Collegiate, Manual Training, Business, Special Courses.
Features.—Modern Residence, Good Equipment, Ideal Location, Splendid Environment. Experienced Teaching Staff. Moderate Cost.
For illustrated Catalogue of information apply to
Principal W. L. ARCHIBALD,
WOLFVILLE - - Nova Scotia.
Next term opens Sept. 4th, 1918.

RELIEF AT LAST
I want to help you if you are suffering from bleeding, itching, blind or protruding Piles. I can tell you how, in your own home and without anyone's assistance, you can apply the best of all treatments.
PILES TREATED AT HOME
I promise to send you a FREE trial of the new absorption treatment, and references from your own locality if you will but write and ask. I assure you of immediate relief. Send no money, but tell others of this offer.

New Entrance Scholarships:

Three of $200 each.
Five of $100 each.

One reserved for Cape Breton.
One reserved for New Brunswick.
One reserved for Prince Edward Island.

To be competed for at the Matriculation examinations beginning September 24, 1918.

New Senior Scholarships:

Three of $200 each.
Three of $100 each.

Tenable during second year, and awarded on results of work of first year.

Lectures in all Faculties for the coming session begin on Tuesday, October 1, 1918.

Write to the President's Office for full information.

THE FIRST WEEK IN SEPTEMBER

Is the beginning of our busy season, but students can enter at any time, and it is well to get the "Ice Broken" before the rush begins.

Tuition Rates and full information mailed to any address.

S. KERR
Principal

THE FALL TERM
OF THE
Fredericton Business College
WILL OPEN ON
Monday, Aug. 26, 1918

There is a greater demand for our graduates than ever.

Get particulars rearding our courses of study, tuition rates, etc., and prepare to enter on our opening date. Descriptive pamphlet on request. Address:
W. J. OSBORNE, Principal,
Fredericton, N. B.

Our Fall Term

opens on Tuesday, Sept. 3. Our business has doubled in the last two years. Our equipment is new and up-to-date. You should attend the School that is progressive.

"What do you think of him?" Mears asked Miss Carter, as the expert's ramrod figure vanished.

"He seems very energetic," the girl responded.

"Energy is what we need," John blithely assured her. "The place is full of dry rot. We need some one to wake us up. Got to speed to hold our own these days, you know."

A little later Moran lumbered in. "Say, John," he rumbled, shifting his quid, "is this here expert to be stoppin' my machines and badgerin' my boys about their motions?"

"Whatever he thinks proper is to be done," said Mears curtly. Did I not make myself clear?"

"Oh, all right," said Moran mildly quizzical. "I just wanted to know."

So out in the factory Mr. Epperson, his horn-rimmed glasses riding high on his projecting nose, his light-blue eyes peering owlishly, penetrated into every corner of the works. He followed the iron pigs from cars to foundry, he watched the assembly of castings into plow bases, he neglected neither wood shop, paint shop, nor warehouse.

Stop-watch in hand, note-book ready, pencil poised, he asked countless questions and made interminable notes, which, at night, he elaborated on a portable typewriter in his room.

A week went by, and one morning he appeared at the office, a sheaf of typewritten manuscript under his arm. "Where is Mr. Mears?" he demanded.

"He left last night on a long-distance call to help one of our salesmen who is trying to close a big deal in North Carolina," Miss Carter informed him.

"That is annoying," compalined Mr. Epperson, removing his glasses. "I am obliged to go to New York today. I have completed my investigation, the result of which is in this report."

"You have suggested many changes?" asked Miss aCrter in acid accents. "I gather you disapproved of everything."

"I was not engaged to be complimentary," said Mr. Epperson stiffly. "I am like a dentist; the more necessary my services, the more painful they are. I have recommended a number of changes."

"May I ask what the most important are?"

"My report was made for Mr. Mears," Epperson informed her, beginning to polish his glasses with a bit of pink paper, "but as you are a stockholder and in position of some importance, I will summarize them.

"I have suggested some new machinery; a different lay-out for the factory; an entirely new office system and certain resignations."

"Resignations?" faltered Miss Carter.

The precise young man replaced his glasses and surveyed the girl with some disdain. "Yes. The most important would be Moran's. Several of the foremen should go also. These men would not fit into any system I could outline.

"Mr. Epperson, do you realize that Mr. Moran helped to found this business? That he, a small stockholder, works for it as loyally as if it were all his own? It would kill him to be asked to resign!"

"I am not here to protect the Morans," said Epperson calmly. "They block the wheels of progress. Get results or get out. Properly run, this can be made a paying business. As now conducted, it will soon be bankrupt."

"Better bankruptcy than to discard like worn-out plowshares the men who made the works," flamed the distressed girl.

"Sentiment pays no dividends," sneered Epperson. "Which brings me to a proposition I have decided to make to Mr. Mears.

"What is it?"

"This is a good field for a properly run plow business. I have some idle money that I should be willing to put with my services into the concern. I have suggested that I take over Moran's stock and become general manager."

Miss Carter gazed at him dumbly.

"I"—Epperson expanded his chest a trifle—"will guarantee to pay dividends at the end of a year."

Almost beside herself with anger, Miss Carter strove to speak, but Epperson, with a superior gesture, waved her aside. "Please ask Mr. Mears," he went on in his brusque way, "to read this report carefully and to consider my appended offer. I shall return in a few days. Good morning!"

For a moment Miss Carter stood dazed. Then as her anger mounted, she felt that she must talk to some one or explode. Burk stood at his ledger, a furtive ear cocked in her direction. She wondered if he had heard. In any case, he was not the confidant she wished, and she sped out to find Moran.

She came upon him in the foundry, up above a cupola, watching a gang of men charge it with broken pig-iron, scrap and coke. The old superintendent's blue shirt was open over his hairy chest and he was spurting tobacco juice into the stack at such regular intervals than an onlooker might have thought it a necessary ingredient.

"Mr. Moran!" the girl cried. "Mr. Epperson has finished his report, and what do you suppose he recommends?"

"I dunno," boomed the old giant in his big voice, trained to carry above the rattle of machinery, "but I'm glad he's done. I'm sick of seein' the four-eyed little owl nosin' around."

The girl stopped for a moment to get her breath, her hand pressed to her side, her face scarlet under its crown of bright hair, for she was panting with exertion and excitement. Her white clothing contrasted sharply with the grimy garb of the busy men. With an imperious gesture she drew Moran aside.

"Epperson wants ever so many changes," she told him.

"The hell he does!" roared Moran. "Excuse me, miss."

She went on slowly. What she felt he must know was not so eaasy to tell him. "He wants to buy your stock—and take charge. He says that—that you—and some of the formen—are too old—that you won't speed up—that you must resign."

If the words brought dismay to the old giant's sturdy heart, his ruddy face gave no sign. His jaws continued

to function with the same regularity. His eyes followed his men.

At last, seeing that the girl expected him to say something, he spat, and mumbled, "Well?"

"Is that all you can say?" she flashed, stamping her foot.

"What is there to say?" asked the veteran. John's away. If he comes back and says this here expert is right, I reckon I'll have to step out. I'm getting old, anyway; reckon maybe it's time I quit."

The girl doubled up her firm little lsts. "I wouldn't give Eperson the satisfaction! I'd fight!"

Moran merely shook his head.

If the superintendent refused to betray any feeling, others did not take the matter so calmly. Before the day was over Miss Carter saw that the news had spread; she guessed that Burk had heard and had talked. Little knots of dark-browed men formed about the yard at noon; sullen glances were directed at the office windows as the hands streamed through the gate at night.

The next morning Mr. Mears came back, as creased and speckless as though he had not spent the night upon the train. He was pleasant, as usual, and just a trifle proud of himself.

"We put it over," he announced in his jubilant way. "We signed them up with twelve counties as territory, and they placed an order for five cars of goods. In two years we'll be selling them a car for every county. That's the beauty of the plow business—the increasing repair trade!

The young president was too pleased to note the absence of Miss Carter's congratulations.

"These orders are for immediate shipment," he explained importantly, "and the season is late. Any stuff that isn't ready must be rushed. By the way, this will give Epperson a chance to get a line on our handling of a rush order. Where is he?"

"He had to go to New York. He has finished his survey and made a report, which is on your desk."

"All right," said John. "I'll read it later. Have Moran come in, will you?"

"Dan," he instructed the superintendent, "here's an order for five cars from the Wilmington Supply Company. To fill it promptly and properly means a lot to us. We must get it right out. How soon can you do it?"

"I dunno," answered Moran, feeding himself a great wad of fine-cut. "Lemme see the specifications."

"Well, what about it?" John hurried the old man, as he went ponderously over the order."

"I dunno," Moran repeated. "We'll have to make some if it. We'll do the best we kin, Johnny."

"Have the order written up and send it out," mumbled Moran through his quid. "We'll do the best we kin; you know you can't hurry iron much, Johnny."

"You see!" No system!" complained Mears to Miss Carter, when Moran had gone. "We ought to be able to tell exactly how long a certain piece of work will take, and all I can get out of Dan is that he'll do the best he can! It's exasperating! If that order is cancelled on account of delay, his best won't be good enough!"

"You gave the Wilmington people long time," Miss Carter nastily changed the subject. "Why did you do it when we need cash so? That steel note falls due next Monday, and it must be paid, not renewed, for they won't let us have any more material until the last is paid for."

"I know; I had to do it," he told her. "We can't hold up a big concern for a sight-draft, bill-of-lading attached shipment. I couldn't let them know our fix. Don't let that note worry you. We'll find the money somehow—I reckon."

The girl looked sharply at him. She saw that anxiety showed beneath his accustomed jauntiness, and she realized that the situation did worry him, whether he would admit it or not.

Mears went to his office. An hour later Miss Carter entered and found him leaning back in his chair, his long legs thrust over a corner of his desk, the famous report in his lap, and an unusually thoughful look upon his face. He brought his feet to the floor as she entered, but he did not quite come out of his brown study.

"Have you read the gospel according to Mr. Epperson?" she asked sarcastically.

"Yes," said John in an absent tone.

"Do you intend to follow his suggestions?"

"Most of them."

"Then there will be radical changes?" The girl could not keep the concern from her voice.

"Why, yes," he answered, with a shade if impatience. "What's the use of paying for advice unless one takes it?"

"And Mr. Moran?" The voice quivered.

"I can't tell you my plans yet," said John. He picked in a worried way at the scarab in his tie. "I haven't fully formulated them. As for Dan—I've been undecided about him for some time."

Miss Carter had no heart to say more. Of course, the president would accept Epperson's offer; the girl had never doubted that, but she had hoped that Mears would find a way to keep Moran. She realized that it would be folly for him to reject the expert's proposition. His advent would lighten Mear's responsibilities by giving him an efficient manager who knew the business to the last bolt. More than all, it would give them what they must have at once, ready money. They were heavily in debt, they needed more material, and five thousand dollars must be paid to the steel company the following morning.

There was every reason for Mears to accept Epperson's offer, and nothing save sentimental scruples to cause him to decline. And yet, Miss Carter's heart ached to think that even at John's greatest need he would drop the man who for years had been a major part of the business, just because he had grown old and slow. She had hoped that Mears wah bigger than that; but still, when she came to question herself, what else could he do?

She determined that she would try to talk to Mr. Mears in the morning. She was too disturbed to do it at once; she would say more than she meant.

But in the morning she found on her desk a brief note from the president, saying that he would be out of town a few days, and asking her to look after the Wilmington order. Miss Carter knew no reason why Mears should absent himself; it seemed to her that he was not acting fairly in leaving at a critical time. Then it flashed upon her that he wished to avoid any discussion of the changes to be made until Epperson came back. In the meanatime—he had underlined it—they were to rush the Wilmington order! Her lip curled.

Her thoughts were interrupted by Burk, who sidled over, and, raising a corner of his mouth as he had seen crooks do in the "movies," rasped: "Put you wise to something; this scheme of Epperson's has leaked out!"

"How? Through you?"

Burk's eyes shifted under the girl's clear gaze, "Don't matter who told it," he muttered evasively. "The men are on, ripe for trouble. They're awful sore about Moran being let out. He's been here most forty years. He's hired half the men; he knows 'em, and their wives, and their kids. Mears don't know the boys from Adam on the street."

"He's hardly had time," Miss Carter reminded.

"Aw, he don't want to know 'em" scoffed Burk. "All he cares about is the coin. The men see Dan about to be thrown out, after all these years, and that smart stiff, Epperson, coming in to drive worse'n Mears. They say what's the use of rushing the Wilmington order and getting chucked afterward?"

"I don't know that I blame them," sighed the girl.

"They're going to have a meeting tonight," the bookkeeper pursued—"the forman and some of the other old hands; kind of secret, you know.'

"Is Mr. Moran in it?"

"Naw, not yet. They've tried to sound him, but he just spits and cusses and tells them to mind their own business. He's promised, though, to meet the boys tonight."

"What do they want to do?"

"Quit cold and tie the factory up. They can do it too. By the time things are straightened out, the Wilmington order will be a goner. They know it's got to be shipped quick, the season's so late."

"Why don't they appoint a committee to see Mr. Mears?"

"What's the use? He wouldn't listen to 'em, and he ain't here, anyhow. Like as not, he figured they'd kick, and skipped on purpose. He didn't figure far enough to see they was ready to walk out for old Dan!"

Burk's diagnosis of the president's absence confirmed Miss Carter's own judgment. Everything pointed that way. And, Miss Carter thought, an appeal probably would have been useless. Mears had harped on efficiency since he had taken charge. He had insisted on engaging Epperson, and he had declared, again and again, that mossback methods must give way to modern practice.

Miss Carter worked wearily through the day, too depressed to discuss the matter further with any one. All through the night she kept waking at intervals to wonder at the outcome of the meeting, and the next morning she hurried to the office, half sick with worry.

Burk was not at his desk, and the girl was in no mood to wait, so she scurried out to find Moran. He was in the foundry, grimly watching the molders prepare the flasks. His figure loomed large as ever among the squatting workmen, but Miss Carter fancied that the old man's heavy shoulders were more stooping than usual.

"What are you going to do, Mr. Moran?" she asked.

"Do about what?" rumbled the giant.

"The meeting last night—Burk told me——"

"Oh, that," growled Moran in disgust. "There wa'n't nuthin' to that. Some of the boys shot off their mouths, but I shut 'em up. I told 'em that what Epperson reported, or what John plans to do ain't got nuthin' to do with what they got to do now—which is to git out that Wilmington order. I told 'em the first man that sulked would git his time."

"Then there won't be any strike?"

"Hell, no! Excuse me, Miss. Think I'd stand for a play like that? Lay down on John in a pinch. His granddaddy and me built this business. I been in it all me life. Maybe it's time for me to git out. I dunno. We change as we git older, I reckon, though I don't feel no different."

"Have you said anything to Mr. Mears?"

"No!" roared Moran, red hot. "What would I say? I ain't goin' to holler and I ain't goin' to resign. If John wants to git rid of me, let him come out and say so. Till he does, my job is to run this factory and git the goods out, and, by the great horn spoon, I'm goin' to do it!"

The girl went back to the office, her own bitterness stilled in part by the old man's steadfast loyalty. Yet she could not but contrast the whimsical lightness of the young president with the sturdy devotion of the old superintendent.

John returned on Monday morning. In a new pincheck suit and scarlet scarf, from his low tan shoes to his smoothly-parted hair, he looked the elegant idler, and if he had any worries, his complacent face did not show them.

He stopped to hand a few papers to Burk, and after a word wiith him came to Miss Carter's desk.

"Mr. Epperson has returned," she hastened to advise him. "He is waiting for you in your office."

Heart Palpitated, Had Dizzy Spells.

Could Not Work For 8 Months.

Palpitation of the heart is one of the most common of all heart troubles, and many people are kept in a state of morbid fear of death, become weak, worn, and miserable, have weak and dizzy spells, their nerves become unstrung and they cannot sleep.

Wherever there is any weakness of the heart, Milburn's Heart and Nerve Pills will strengthen it, and build up a strong healthy system.

Mrs. Walter Grieves, Apsley, Ont., writes: "I had been run down and doctors told me I was anæmic, but did not help me with their medicines. I could not sleep nights, my heart palpitated so, and I could count every beat. I used to have such dizzy spells I would have to go to bed. I was not able to do my work for eight months. A cousin of mine had taken Milburn's Heart and Nerve Pills and told me what they had done for her. I took eight boxes of them, and now I am able to help every day with the work. I am so thankful to tell others what they have done for me, so that they may try this great and wonderful remedy. I hope this may prove good to some one who is suffering the way I did."

Price, 50c. a box at all dealers, or mailed direct on receipt of price by The T. Milburn Co., Limited. Toronto, Ont.

"Fine," exclaimed John "See him in a moment How about the Wilmington order?"

"All gone but the last car—I'll find out about that." Miss Carter answered.

"Bully!" sad Mears.

"By the way," Miss Carter called, as the president turned, "what about that steel note? It falls due today and we haven't the money to meet it."

"Oh, that'll be all right," returned John casually. "Wait until I see Epperson and I'll tell you about it."

He entered his own room before the girl could question him. Undoubtedly he had made up his mind to accept Epperson's offer. It was unlikely that anything she could say would influence the president, yet she resolved to try. She sprang up to folow him into his office.

As she opened the door, Moran rolled in, the bills for the last car in his hand. "John come back?" he asked. "Thought he'd like to know we got the stuff all out."

"Tell him," the girl snapped bitterly, and pushed the old man ahead of her into the private office.

Epperson was saying: "When will you be ready to discuss my rejort?"

"Right now," smiled John. "I've made up my mind."

Moran advanced holding out the bills-of-lading. "The Wilmington order has went," he rumbled in his heavy voice, too big for the little office.

"That's good," observed John, looking up absently. Then as Moran turned to leave, he called after him: "Wait a moment, Dan; you had better hear this."

The old superintendent came to a stop, edged back, and waited stolidly.

Miss Carter felt herself trembling. Was Mears going to sentence the old man so badly before them all? It was cruel. Even the unemotional Epperson seemed surprised, and stammered:

"You—you say you have made your decision? Er—what are you going to do?"

"Adopt your ideas, of course," declared John. "The report's a model; finest thing I ever saw. Your plans are bully in the main, although I can't quite see my way to do everything you recommend."

"Some of the minor changes may not need to be made at once," chimed Epperson, highly pleased and disposed to be easy in his victory. "And as to my proposition to put in some money and take hold?"

"Ah, that is another thing, Epperson," John drawled, "and the one I couldn't see my way clear to do. I have no doubt that you could produce dividends, but I don't believe you would fit into our little family. I know I can make Dan see the wisdom of your system, but we couldn't get along without Dan."

John beamed pleasantly upon the little company, and, squinting across his desk into the mirror which he had hung in the old office, straightened his scarf the least degree.

"Then you don't think Mr. Moran is too old to run the shops?" Miss Carter gasped.

"The way the Wilmington order has been handled proves that nothing fundamental is wrong," laughed Mears, "On the contrary Dan is getting so spry I think we had better boost his salary a bit. That is what I had in mind the other day," he continued, turning to Miss Carter. "but I wanted to see how the big rush order came through."

Mr. Epperson had risen to his fect. His light-blue eyes glared through his horn-rimmed glasses. "There is no reason, then, why I should detain you longer," he said stiffly.

"Only to let us thank you for your very able services," said John.

Miss Carter followed the expert out. The narrow bookkeeper was slipping into his coat.

"Where are you going?" she asked.

"To deposit this check," he explained, showing her a slip of thin paper. "Mr. Mears went down to Norfolk and squeezed that big past due account out of old Robinson. Say, the boss is a hustler, ain't he?"

Miss Carter's eyes were blurred with moisture. As she dabbed them clear she saw Mears and Moran come out of the private office, the young president's pin-checked arm laid affectionately upon the old superintendent's blue flannel shoulder.

Montreal, May 29th, '09.
Minard's Liniment Co., Limited,
Yarmouth, N. S.
Gentlemen,—I beg to let you know that I have used MINAR'S LINIMENT for some time and find it the best I have ever used for the joints and muscles.
Yours very truly,
THOMAS J. HOGAN,
The Champion Clog and Pedestal Dancer of Canada.

TRAVELLING WITH CHILDREN

One who has oportunity to observe the relations of parents and children on trains cannot avoid becoming convinced that parents are not good traveling companions as a rule. It seems that at least nine out of ten parents think a child of any age when traveling should sit in his seat and "behave himself." One often hears a parent speaking roughly to his children if they stand up in their seats to look around at the people about them, or if they try to run up and down the aisle, or swing between the seats and so on. The parent does not wish to do these things himself, so why should his children wish to do them? Many parrents treat their children on a train as though they were mischievous when they will not sit in their seats.

The majority of children from the ae of three to fifteen or thereabouts want to look out of the window when they are on a train. If the weather will permit they want to have the window up and put their heads out a few inches. It is a fascinating experience for a child to watch the objects and to feel the air rushing past him. Most parents will not allow their children to have this fun; if the children persist in their attempts to gain the experience the parents will punish them. This is unfortunate. Most children run no danger whatever in doing this. The parent could easily keep an eye on an adventurous child to see that he did not reach out the window too far. A single word would be enough to cause such a child to play safe.

Traveling is a fatiguing process for children, mainly because it prevents freedom of muscular action. At best a child is greatly restricted in his movements. So he develops tensions and becomes restless; and unless he can find relief for his tense nerves he will become disorderly. This is why nature urges him to push his head out the window and pull it back again, jump up and down in his seat, run to and fro in the aaisle, swing between the seats and indulge in other motor performances.

The typical parent seems to be in terror lest somethiug will happen to his children on a train if he gives them any leeway to move about. If they move toward the door of the car he thinks they will certainly fall off the rtain and be run over. So you can hear him calling to them to come back and sit down. But the records of accidents on trains show that children who are traveling are practically never injured. There is hardly a possibility of a child falling off a train by going to the door of the car to observe what is taking place. Most children are very cautious about taking chances in respect to this matter. They could be trusted to keep out of danger without the parent saying a word to them. If the latter thinks there is danger he ought to stand near enough to the child so that he could protect him in case of need.

The writer has made observations on a number of trains recently to find what means parents provide to divert their children from running up and down the aisle and performing other forbidden acts. Rarely does a parent think of taking in his satchel an interesting book or two which he can read to his children, or a game like checkers which he can play with them. But if the children ever need to be read to it is certainly when they are travelin. The noise and movement and general excitement tend to overstimulate them, and their attention should be held to quiet and interesting things for some part of the time while they are on a train. This can best be done by interesting them in an attractive story or in pictures or quiet games. A parent who is starting on a long trip and does not make provision of this sort is foolish. There will certainly be unceasing strain and stress between him and his children; and it will be disagreeable not only for all the travelers who cannot avoid being irritated when they observe parents repressing and even punishing children who are trying to release tensions developed by the restraints of the train.

TO IRON LINEN CENTERPIECES

Iron first without starch, then place centerpiece carefully on board, put over it a thin, smooth cloth dipped in cold starch and iron dry. They will retain their shape and look new.

JUNKET

1 quart of milk.
1 junket tablet.
½ teaspoonful of vanilla.
3 tablespoonfuls of sugar or sugar to taste.

Heat the milk until warm, but do not bring it to the boiling point; add the sugar and flavoring, and the junket tablet, which has been dissolved in two tablespoonfuls of cold water. Mix quickly and pour into ice-cream glasses or custard cups. Set in a warm placc until congealed—about thirty minutes—then set in a cold place. Be careful not to shake the glasses or cups. It is important to have fresh whole milk when making junket.

BERRY MILK SHERBET

1 quart of milk.
1 cupful of berry juice.
1 cupful of sugar.
1 tablespoonful of lemon juice.

Put the sugar and fruit juice into a bowl; stir until the sugar is dissolved; put the milk into a freezer that has been packed in ice and salt (three parts ice and one part salt); then add the fruit juice and lemon juice. Turn at once. Raspberry, strawberry and loganberry juices are used the same way, or one may use fruit juice from rich canned fruits or berries, using sugar to taste.

FROZEN CUSTARD

1 quart of milk.
1 cupful of sugar.
2 eggs.
4 tablespoonfuls of cornstarch.
1 teaspoonful of salt.
½ teaspoonful of Vanilla extract.

Beat the eggs and sugar until well mixed; then add the cornstarch, which has been mixed with a little cold milk. Add all to the hot milk in a double boiler. Cook for thirty minutes; cool and add the salt and flavoring. Freeze. Half a cupful of fruit, chopped fine, may be added when the custard is partly frozen.

MILK SHERBET

1 quart of milk.
1 cupful of sugar.
1 tabelspoonful of vanilla.

Mix these ingredients and freeze the mixture in the manner described in the recipe for berry milk sherbet.

PALMER'S
Summer Packs
for the S.O.S.
JOHN PALMER CO. LTD
MOOSE HEAD BRAND
FREDERICTON
You can't enjoy farm labor with tired, aching feet. So, boys, slip your feet into Palmer's Summer Packs. Made from durable yet soft, pliable, oil-tanned, Skowhegan waterproof leather—the ideal farm shoe for comfort and wear.
Easy to put on and take off. Large eyelets, quickly laced. Solid leather heel, sole and insoles. Bellows tongues.
Ask your dealer to show you "Moose Head Brand"

MOTHER AND CHILD VERY LOW WITH DYSENTERY.

Dysentery is one of the worst forms of bowel complaint. It comes on suddenly, the pains in the bowels become intense, the discharges occur with great rapidity, and are very often accompanied by blood, and the action on the system so weakening that its termination often proves fatal.

When the bowels get loosened up in this way, and you wish to check the unnatural discharge without bringing on constipation, there is only one remedy to use, and that is Dr. Fowler's Extract of Wild Strawberry.

Mr. W. J. Metcalfe, Tofield, Alta., writes: "I wish to state that we have used Dr. Fowler's Extract of Wild Strawberry with good results. I can say that it can't be beat. It saved my wife and little boy last summer, when they were very low with dysentery. We always have a bottle of it in the house, and would not be without it if it cost five dollars a bottle."

"Dr. Fowler's" is not an experiment but a tried and proven remedy that has been used in Canada for the past 72 years.

There are many cheap imitations and substitutes of this sterling remedy on the market. Beware of them and accept only the original when you ask for it, as these cheap no-name, no-reputation, so-called strawberry compounds may be dangerous to your health. The genuine is put up only by The T. Milburn Co., Limited, Toronto, Ont. Price, 35c.

CHILDHOOD

By Charlotte Conkright Kinney

What if God had not put children on the earth,
But only grown up men and women!
Though men were kinder, women lovelier,
And all fair things,—the Flowers, Birds and Butterflies
Were twice as fair,—but still there were no Children
No tramp of little feet in play,
No shout of joyous laughter,
No nesting heads against our breast,
No twining arms around our neck,
No dancing eyes, nor tender lips—
O! then, Dear Heart, this World would be
A place too weary
Far too dreary
To live in—You and Me!

THE BACTERIOLOGY OF DISH-WASHING

The modern housewife is keen on the subject of eliminating the germ. Never before in the world's history has the poor genus bacterium been so ceaselessly harassed and persecuted as he is to-day. On every side he meets the housewife armed to the teeth with dustless dust mops, germicides, antiseptic sprays, vacuum-cleaners, and fumigators. Still, he doesn't seem to lose hope; and perhaps it is because Mrs. Up-to-Date Housewife has left him one loop-hole. He can still find entrance into our best families via—the dish water.

The following article by E. W. Elsom in a recent number of the Mother's Magazine, brings this matter very forcibly to the attention of the public.

While women have been keeping close tab on the sanitary and hygienic condition of their homes, watching the water and the milk supplies, and insisting on careful inspection of meat and other foods, they have to a large measure neglected to make any changes in their methods of dish-washing.

This neglect has occurred, perhaps, because so few women realize what an important part dish-washing methods may play in the spread of disease. Its effects are so hidden, so difficult to track back to their true source, that contaminated dish water often escapes any shadow of suspicion.

Every now and then, however, the facts of a startling case are unearthed, and we get some idea of what a leading role unclean dishes may play as germ spreaders. Not long ago an epidemic of typhoid fever broke out among the students in a Wisconsin town. Forty-three cases were reported, and several deaths resulted, before the epidemic was traced to its source—a "typhoid carrier" who was wiping dishes in a local restaurant.

Yes, you may say, that may happen in a public establishment, but in my own home, my own kitchen, there can be no danger.

But, just a minute! One woman, impressed by the facts of this epidemic, proceeded to make a careful study of dish-washing and dish-wiping in the home from a bacteriological standpoint.

The results of her investigations were interesting and startling.

She found that an ordinary dinner plate, as it leaves the table in the ordinary household, has on it anywhere from 30,000 to 90,000 bacteria, the average number being about 60,000. Most of these were harmless bacteria; still, if the plate were such fertile ground for harmless bacteria, it would make a rich culture for dangerous disease germs.

Next a long series of experiments were carried on, to learn how many bacteria were left on these plates after they had been washed. The dishes were washed in water of differing temperatures, and rinsed in lukewarm water, and hot water, and boiling water, and then the bacteria were counted under a microscope.

From the standpoint of the housewife the astonishing and significant fact disclosed is this:

The average dinner plate, when washed in lukewarm water and dried without rinsing, was found to have on its surface 250,000 bacteria, or almost five times as many as it had when brought soiled from the dinner table!

This statement may seem amazing and improbable; but a little thought will show that it is logical, and the result what might have been expected. What are the necessities for rapid bacterial growth? Warmth and food. And what does the housewife give to those bacteria when she puts a lot of dinner dishes in lukewarm dish water? Warmth and food!

Thousands of housewives are still washing dishes in water no hotter than they can bear their hands in. It is not hot enough to kill bacteria; in fact, it encourages them.

So they multiply and increase, and the dishes that are taken out of this water have on them five times as many germs as they had when put into it.

This source of danger can be eliminated from the household by the use of hotter dish water and the careful rinsing of dishes in boiling water.

An investigation shows exactly the relation of the temperature of your dish water to the number of bacteria left on your plates, and cups and saucers, and silverware. It shows that the hotter the water, the fewer the bacteria left alive, and hence the smaller the danger of the spread of diesase in your family.

It is not enough that your dishes merely look clean. The dishes used in these experiments came out looking bright and shiny and clean.

The experiment showed that the only way to have sterile dishes is to use boiling dish-water, and boiling rinsing water. In large institutions where a dish-washing machine can be used, this sterilization can be attained easily. In the ordinary household it is less convenient to use boiling-water.

But the housewife should take every precaution to have clean dishes on which to serve her meals. There are six rules by which one may achieve the maximum of cleanliness in dish-washing:

First: Carefully scrape all plates and platters before washing.

Second: Do not allow anyone recovering from any form of contagious disease to handle dishes during washing.

Third: Do not cough or sneeze while working with the dishes.

Fourth: Have the dish-water hot. Use a dish-mop.

Fifth: Rinse all dishes in boiling water.

Sixth: Use clean dish-cloths and dish-towels.

FEEDING THE YOUNG CHILD

Children's diet during hot weather between the ages of two and six deserves more attention than it receives. Many a child who was tenderly safeguarded during his second Summer is sadly neglected through his third. In planning a hot-weather diet for young children, a few fundamental principles must be remembered.

First—There is more danger of overfeeding than underfeeding in Summer. A child will thrive on from one-fourth to one-third less food in Summer than in Winter.

Second—Stale, fermenting fruits are as dangerous to the child of four or five as unclean milk is to a babe of nine months.

Growing children must have the food elements which build bone, teeth, tissue, muscle, and brain. Of meat, fish, eggs, milk, and cereal which serve this purpose, milk is most easily digested, therefore the child between two and six needs at least one quart of milk daily in hot weather.

For oatmeal and corn-meal mush, which create heat, serve rice, cracked wheat, hominy grits, farina, and tapioca.

In supplying meat, remember that a small quantity of very good meat, properly prepared, is far more desirable than a larger quantity of less nourishing meat. Stewed or boiled meat with thickened gravies is especially bad for children in Summer. Better serve meat every second or third day only, and let it be a chop or bit of steak carefully broiled. Poultry, boiled, broiled or roasted, and fish, boiled or broiled, may be substituted for beef or lamb. Neither pork, fresh or smoked, nor veal should be served to children in hot weather. Eggs may be served in moderation, soft-boiled, or poached.

But it is in the selection and preparation of vegetables for young children that most of us err. Here is a list of vegetables forbidden to children until they have cut their second teeth: Raw celery; raw or fried onions; radishes; cucumbers; raw, fried and baked tomatoes; cabbage, eggplant, pickled beets.

Creamed celery, creamed onions, Brussels sprouts, peas, string-beans, Lima beans, and asparagus tips are permissible. Tomatoes stewed for several hours, in an agate pan, sweetened slightly and thickened a little with barley or rice flour, grated breadcrums or crackers may be served occasionally. There is a difference of opinion concerning carrots, but the average specialist in the care and feeding of children permits young carrots if they are well cooked and thoroughly mashed with a little broth, not butter. Young beets can be treated the same way. For children, corn is one of the most enticing vegetables on the family dinner-table—and one of the least digestible if eaten from the cob. Here, however, the mother may compromise. Boil the corn on the cob in salted water for ten minutes; drain, score each row of kernels with a sharp knife, and with the back of the knife press out the pulp. Thus, freed of its indigestible hull, the pulp may be served with safety to a child as young as three. For children from four to six, corn may be grated from the cob and served as a pudding, with milk, egg, and salt.

Save all water drained from boiled vegetables and use for flavoring milk soups, which are fine Summer food for children. Allow one part milk and two parts vegetable water, and to each quart of liquid one heaping teaspoonful of flour and scant teaspoonful of butter rubbed together until smooth. This makes a creamy soup which children like.

Of all Summer foods, however, fruit has the most dangerous possibilities. If under-ripe, stale, or overripe, it causes fermentation. Only perfectly formed, fresh fruit is fit to eat raw, yet because Summer is the fruit season, all fruit seems desirable.

For children under six, cooked fresh fruits are always safer than raw. Only when the flesh of an apple is mellow and of rosy or creamy tint, sohuld it be eaten raw. Then it must be carefully pared and cored, and, for three-year-olds, scraped soft with a spoon. Pears, like apples, may be stewed and baked Peaches may be eaten raw if in perfect condition, and carefully peeled. Berries and small fruits should be rubbed through a coarse sieve, or, better still, stewed without sugar if sweet, or with very little sugar if tart. Children who eat strawberries must be watched carefully for after-effects. These delectable berries sometimes cause a rash which indicates a disturbance of the digestion or kidneys, in which case they must be stricken from the diet list.

Summer Drinks for Children

Fruit juices may be used as a Summer beverage. The best way to pre-

GENUINE DIAMONDS

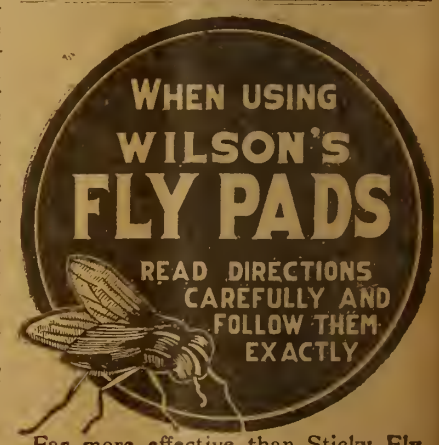
JACOB BROS., Diamond Imp., 15 Toronto Arcade, Toront

LET a woman ease your suffering. I want you to write, and let me tell you of my simple method of home treatment, send you ten days' free trial, postpaid, and put you in touch with women in Canada who will gladly tell what my method has done for them.

A MESSAGE TO WOMEN!!

If you are troubled with weak, tired feelings, headache, backache, bearing down sensations, bladder weakness, constipation, catarrhal conditions, pain in the sides, regularly or irregularly, bloating, sense of falling or misplacement of internal organs, nervousness, desire to cry, palpitation, hot flashes, dark rings under the eyes, or a loss of interest in life, write to me to-day. Address:
Mrs. M. Summers, Box 309 Windsor, Ont.



Far more effective than Sticky Fly Catchers. Clean to handle. Sold by Druggists and Grocers everywhere.

FIRST AID IN THE KITCHEN

Mends Leaks in Graniteware, Tin, Aluminum, etc., in two minutes without tools. Saves a kettle for half a cent. At dealers or from us, 15 cents.
Vol-Peek Co., Box 2024, Montreal, Can.
VOL-PEEK

pare them is to cook the berries or fruits until tender, strain through a fine sieve or a bag of coarse cheesecloth, and return to the fire with sugar, allowing ¼ pound of sugar to 1 pint of fruit juice. Simmer fifteen minutes, skimming as for jelly, remove from the fire, bottle an set away in a cool dark place until needed.

Dilute according to the richness of the fruit and serve between meals in place of ginger ale, root beer, soda, pop and other soft drinks—made from unknown ingredients.

THE CHICKEN DINNER FOR NEXT WINTER

If you have a small flock, you can lay away your chicken dinner for next winter now. "Can the cockerels when it no longer pays to feed them. This will put on your pantry shelves material for the chicken dinner when poultry is scarce and prices high. The following directions are being supplied to boys' and girls' poultry clubs on "Canning the cockerels."

Kill fowl, dress at once, cool; wash thoroughly, draw, then cut into convenient sections. Dip into cold water to insure cleanliness. Place in wire basket or cheesecloth and boil until meat can be removed from bones easily. Then remove from boiling liquid to separate the meat from bones. Take the meat off in as large sctions as possible; pack hot meat into hot glass jars or enameled cans; fill jars with hot liquid after it has been concentrated one-half; add level teaspoonful of salt per quart of meat for seasoning; put rubbers and caps of jars into position. not tight. Cap and tip tin cans. Sterilize for the length of time given below for the particular type outfit used:

Water bath, homemade or commercial (quart jars).....3½ hours.
Water seal, 214 degrees.....3 hours.
5 pounds steam pressure....2 hours.
10 to 15 pounds steam pressure 1 hour.

Remove jars, tighten covers; invert to cool and test joints.

Caution.—Only the very best types of rubbers should be used.

floicsy onlcer| ocwok tCagv hyo gpE.i

A HARMLESS FLY POISON

Mix thoroughly one-half cupful of sweet milk, one egg yolk and one teaspoonful each of sugar and ground black pepper. Spread on white plates wherever there are flies. When dry put out a fresh mixture.

A TIME-SAVER

Save time in preparing vegetables, by cooking such as parsnips and carrots with the skins on. When cooked you can peel them off very easily.

SCORCHED MILK

When heating milk for soup, if a small amount of butter be rubbed over the bottom of the stew-pan, the milk will not scorch easily.

BUTTER FOR BUMPS

Children are continually falling and getting bumped. If a little butter is applied as soon as it happens the flesh will not turn black-and-blue.

KEROSENE FLAMES

If fire is caused by upsetting a kerosene lamp, throw on flour, never water. The flour will extinguish the blaze; water only spreads it.

EMPTY SPOOLS MADE USEFUL

Keep all your empty spools and take them with you to the summer cottage. They are useful to slip over the nails used for hanging garments and will save you many a tear and rusty spot.

HOT-WATER BAGS IN YOUR SHOES

Cut pieces of rubber the size and shape of your shoe-sole from an old hot-water bag, slip them in your shoes, and they will be protection if the soles are thin.

"How do you do it?"

"Do what?"

"Work all day long with back bent over your crops—and return from the fields apparently fresh and vigorous for your chores."

"My father did it before me."

"I know that. But what is the secret? How do you do it? As for me I go to bed tired out and after a few hours' work in the morning, begin to wish I had never been born."

"Many years ago our family began to rely upon the advice of Dr. Chase. Away back in 1864 we managed to get a copy of his book. Since then we have had many copies. And each new book retaining all the virtues of the old, contains something new and valuable. Dr. Chase has kept our family posted on the progress of modern science as regards health."

"Humph! I have always looked upon Dr. Chase's remedies as patent medicines."

"The parts of your self-binder, of your mower, of your separator, and of all the machines you use on the farm, are patented. Does that make them less valuable? A thing is neither good nor bad because it is patented. USE ALONE PROVES VALUE. And thirty years of use has proven the worth of Dr. Chase's medicines to our household."

"There is something in what you say."

"There is more in what I am able to do, as a result of following Dr. Chase's advice. There was a time that my back bothered me so that I could not stand hoeing, pitching hay and such work but by using Dr. Chase's Kidney-Liver Pills as a regulator of the kidneys, liver and bowels, I got rid of backache and back weakness."

"Well that is just where my weak point is, in the back."

"Try Dr. Chase's Kidney-Liver Pills and if I don't miss my guess, you will soon be all right. We have found the occasional use of these pills the best means of keeping these organs regular and thereby avoiding pains and aches, as well as the development of serious disease."

"I will certainly give them a trial for I have often **wondered** how you have kept so well and fit."

Dr. Chase's Kidney-Liver Pills, one pill a dose, 25c. a box, at all dealers or Edmanson, Bates & Co., Ltd., Toronto.

HOUSEHOLD HINTS

At every meal, if necessary, preach the gospel of the clean plate.

Rye mush may be cooked in boiling salted water like any other cereal.

Matting that is soiled and does not respond to washing can be painted over with a coat or two of paint and look as good as new.

Lumpy batter is a sore trial to the housekeeper, but if she will mix the salt with the flour before wetting the latter, it will often prevent the lumps from forming.

Cleaning copper or brass isn't the most agreeable of tasks and once it is cleaned we should like it to stay clean if not indefinitely, at least for a long time. Your wish can be partly realized if you rub the polished metal with the beaten white of a negg.

Pecan nuts, as everybody knows, are not easy to crack so as to keep the meats even partially whole, but if boiling water is poured over the nuts and allowed to cover them for about twenty minutes or so you will find that the meats will not crumble and will come out in quite large pieces.

Beets, if they are red, add an attractive touch of color to the table, but if they have accidently lost their color they are not pleasing to the eye. In such an event, the beets may be made a brilliant red again if a little red fruit coloring is added to the vinegar.

Never throw away an old silk strainer. The holes can be plugged and it can be used for an ash tray.

Red ants will not eat nutmeg. It hurts their teeth.

MARKETS.

MARKET REPORT

Charlottetown

Beef Carcass 14c to 18c. Retail best cuts 22c to 28c.
Veal, Carcass 14c. Retail 16c to 20c.
Hogs, none.
Lamb, Carcass 30c. Retail 32c to 36c.
Mutton, Carcass 18c. Retail 22c to 24c.
Beef Hides, 16c lb.
Sheep Skins, 75c to $1.00 each.
Calf Skins, 30c lb.
Potatoes, old, $1.30 to $1.50 busel. New, $2.00 to $2.20.
Carrots, new in retail way only and impossible to give price.
Turnips, none.
Parsnips, none.
Oats, $1.00 to $1.05 for black; 90c to $1.00 for white.
Cornmeal, $4.25 to $4.40 per bag.
Bran, $2.15 to $2.20, very little available.
Oatmeal, $6.50 per bag, $13.25 per barrel wholesale.
Middlings, scarce, $2.40 to $2.50 per bag.
Cotton Seed Meal, none.
Oil Cake. $3.50 to $4.00 per bag as to quality.
Buckwheat, none.
Ontario Flour, $11.75 to $12.00 in bags, 20c higher in wood.
Manitoba Flour, $12.00 to $12.50 in bags, 20c higher in wood.
Chickens, none.
Fowl, none.
Turkeys, none.
Geese, none.
Butter, creamery, 42c to 48c.
Butter dairy, 38c to 42c.
Cheese, cheese board last meeting was 22¼c for whole cheese; this is the price the factory men received at their nearest station. The wholesale price to the retail trade is 23½c for whole cheese and 24c for twins. The larger retail stores and for shipment to the wholesale houses through the Maritime Provinces the price would range between 22½c to 23c for wholes with regular ½c extra for twins.
Eggs, 42c to 43c, wholesale prices to county shippers.
Hay, loose, 55c to 65c per 100 lbs., new; pressed, $1.00 per 100 lbs., old.

MONTREAL

Dairy Produce Trade

Montreal, Aug. 24.—The receipts of butter today were 242 packages, as compared with 25 for the same day last week, and 98 for the corresponding date a year ago. There was nothing new in the market to note today, business being rather quiet both in a wholesale and a jobbing way and prices were unchanged.

We quote wholesale prices as follows:

Finest creamery	43½c to 43⅜c
Fine creamery	43c to 43¼c
Finest dairy	38c to 38½c
Fine dairy	36c to 37c

The receipts of cheese today were 7,522 boxes, as against 7,443 for the same day last week, and 9,255 for the corresponding date a year ago. The tone of the market was steady with a good demand from exporters for all supplies coming forward. There was some business done in small cheese for domestic consumption at 22½c to 22¾c per lb.

The Dairy Produce Commission is paying the following prices:

No. 1 cheese	28c
No. 2 cheese	22½c
No. 3 cheese	22c

The Provision Market

Montreal, Aug. 24.—The feature of the live hog situation was the weaker feeling which developed at other Canadian markets yesterday owing to the indifference on the part of packers as to supplies and in consequence there was little or no competition for the offerings, consequently prices at the Toronto market dropped 75c per 100 lbs., with sales at $19.75 per 100 lbs. weighed off cars, and at $19.50 fed and watered, and at Winnipeg prices also declined 75c per 100 lbs., with sales of selected lots at $19.25 per 100 lbs. weihed off cars. This naturally created an easier feeling in the market today and prices were 50c per 100 lbs. lower, the top figure realized for selected lots being $20 per 100 lbs. weighed off cars. There was no change in prices for dressed hogs, but the tone of the market was easy in sympathy with the above. The demand for small lots was steady and sales of abattoir fresh-killed stock in a wholesale jobbing way were made $29.50 to $30 per 100 lbs.

A fairly active trade continues to be done in most lines of smoked and cured meats for local and country account and as supplies of such are not in excess of the daily requirements, the tone of the market remains firm and prices are unchanged. In a wholesale jobbing way sales of 8 to 10-lb hams were made at 37c to 38c per lb., 12 to 15 lbs at 35c to 36c, and heavier weights at 34c to 35c, while breakfast bacon sold at 41c to 42c, Windsor selected bacon at 45c to 46c, and Windsor boneless bacon at 48c to 50c. There was no change in prices for barreled pork, but the trade was quiet with car lots of Amercan bean pork quoted at $43 per barrel duty paid, clear sort cut pork at $49, and clear cut back pork at $59.

A steady trade continues to be done in lard in a wholesale jobbing way and the market is moderately active with no change in prices to note. Sales of Canadian pure lard were made at 32c per lb. in 20-lb. wood pails and at 33c per lb. in 1-lb. blocks, while American compound lard sold at 27c to27½c per lb. in 20-lb. wood pails.

Chicago, Aug. 21.—In the dull atmosphere of the provision pit a little profit taking was sufficient to offset demand from scattered commission houses. Future quotations were:

	High.	Low.	Close.
Mess pork, per bbl.—			
Sept.	$44.20	$44.00	$44.10

PLAN TO VISIT THE

Tractor---Truck---Power Demonstration

FOR ALL EASTERN NORTH AMERICA AT

Cobourg, Ontario, September 17-18-19-20, 1918

Not a competition. A Demonstration.—No prizes.

It will be a great Educational Event. The advantage of Power Farming will be brought home to the Farmer in a practical and effective manner. This Demonstration will, in the range of variety of Labor-Saving Machinery shown, far eclipse anything of the kind ever before held in Eastern North America. No up-to-date farmer should miss it.

You will have the opportunity to compare the work of Horses and Tractors.

There will be a Tractor to fit every size of farm and every size of pocket-book. There will be a hundred of them on the grounds.

Greater Production is the slogan of the Farmer today. How to achieve it with reduced man-power is his problem. Improved Power Farm Equipment is the Manufacturers' answer.

Bring your Ladies.

The tractor won't be the whole show. Lighting plants, Threshing Machines, Grain Separators, Milking Machines, Power Silo Machinery, Water Systems, Tractor Plows Dairy Equipment, and many other lines of Belt Power Apparatus designed to lighten the burden of the Farmer and the Farmer's wife, and increase their productive power, will be exhibited.

Hours spent at Cobourg will mean DOLLARS in your pocket and MORE FOOD for our Soldiers.

COUNTRY PRODUCE

Montreal, Aug. 24—There is little change in egg prices, the trade paying from 41c to 45c delivered, with circles receiving up to 47c f.o.b., shipping point. One sale of two hundred cases is reported from Toronto at 45½c delivered. Some consumers in Montreal buying in twelve and thirty-dozen case lots are paying 50c f.o.b., shipping point, to producers. One retailer is paying 50c to 55c to producers. The demand for high grade stock continues and jobbing prices on extras and No. 1's are firm.

The western market is firmer in Winnipeg, and there is in Alberta a slight increase in receipts. The weather is reported to be cooler, and more favorable to production. In the Maritime Provinces production has fallen off, but conditions are favorable to the young stock, which is reported to be vigorous, and growing rapidly.

The car-lot movement from the west continues, three cars now rolling east from Winnipeg. The price on such shipments ranges around 42½c to 43c f.o.b., Winnipeg. All car-lot shipments have been inspected and between May 28th and July 30th, eighty-four cars have moved in inter-provincial trade, all these (1,109,040 dozens) being produced in the three prairie provinces. These eggs have moved to the larger consuming centres, viz.: Montreal, Toronto, Sudbury, Fort William, Sault Ste. Marie and Hull in the east, and Calgary, Vancouver and Victoria in the west. These have been for the most part fresh gathered, but some cars of storage firsts have also moved.

During the past week the sale of two cars of May storage stock at 45c, storage charges paid, is reported from Toronto. In parts of the west the lower grade storage stocks are being drawn on to help to meet the local consumptive demand.

A firm feeling prevails in the local egg situation and prices show no change. The demand today was quieter from local buyers and in consequence the volume of business was smaller, but on the whole the movement was fair. The receipt today were 736 cases, as compared with 928 for the same day last week, and 1,447 for the corresponding date a year ago.

We quote wholesale prices as follows:

Selected new laid eggs.....51c to 52c
No. 1 stock.....47c to 48c
No. 2 stock.....45c to 46c

Poultry.—Light receipts of poor quality is reported from Winnipeg, and this also applies in Eastern Canada. In Montreal and Winnipeg packers are reported crate feeding. Prices are practically unchanged from those quoted a week ago. Receipts continue heavy on the Edmonton market and are reported to be increasing on the Vancouver market. In Saskatchewan a few dressed fowl are reported arriving on the Moose Jaw market, but no surplus for storage is in sight.

In the United States the poultry markets are steady, and in New York a partial settlement of the Hebrew chicken killers' strike brought the live poultry market once more on a normal basis. The slaughter houses have to pay killers two cents a head.

New York, Aug. 21.—Eggs irregular. Receipts, 19,147 cases. Fresh gathered extras, 49c to 50c; fresh gathered, regular packed, extra firsts, 46c to 48c; do firsts, 42c to 45c; state, Pennsylvania and nearby western hennery, whites, fine to fancy, 66c to 68c; state, Pennsylvania and nearby hennery, browns, 52c to 55c; do. gathered, browns and mixed colors, 38c to 50c.

The Prince Edward Island Exhibition and Horse Races

---AT---

Charlottetown, Sept. 24 to 28, 1918

OPEN TO ALL CANADA. OVER $10,000 IN EXHIBITION PRIZES

FRANK R. HEARTZ, President. *C. R. SMALLWOOD, Sec'y-Treas.*

VALUE OF GOOD ROADS

(Continued from page 713)

road money that is spent on roads is spent on maintaining dirt and similar roads that are altogether impassable. In the light of Canada's resources and the part they will play in the social and material welfare of her people, it will be criminal to let them go to waste or remain unused because of impassable or inefficient roads. The need for good roads is tantamount with the need of most any other improvement in the country and petty objections to their construction are not patriotic. It is a comparatively easy matter to prove that this war is a contest in transportation, and it is equally certain that the future peace time struggle to reclaim industrial freedom lies along the routes where transportation of the country's products are made easy; for these products only become an asset when they are made available through speedy transportation.

THE SHEEP BARN ON FARM THAT IS INEXPENSIVE AND LEADS TO GREATER PROFITS

To realize the attractive possibilities of keeping sheep, a farmer must give each animal a favorable opportunity to live in health and comfort by supplying the necessary buildings and equipment. Sheep raising has passed the period of speculative possibility and is rapidly coming into its own in Canada, chiefly owing to the place it is assuming as a business proposition, encouraged by the increased high prices of mutton and wool. But there are other points to be weighed in keeping sheep. Not only may they be used to utilize so called waste land, but they convert into mutton and wool much material that cannot be utilized by other animals. Weedy cattle pastures into which sheep have been turned have been found to carry the sheep and an added number of cattle after the weeds were destroyed and the grass given a fair chance for growth.

Shelter for Sheep.

Contrary to general opinion, sheep as well as any other class of farm animals require clean, dry shelter. It is especially important that the feet and fleece be kept dry. If their quarters are dry and clean, sheep will stand very cold weather without discomfort or disease. There must be ample ventilation, for sheep if closely crowded sweat badly and quickly use up the oxygen in the air, but there must be no drafts, for contrary to averae opinion, sheep are very subject to colds. In the ordinary climate the sheep barn may be constructed of one thickness of matched boards. It should be large enough to avoid crowding. Windows enough to permit lots of sunshine to enter, and clean, dry bedding under foot are necessities. The lambing pens should be of warmer construction than the general shed. This roughly outlines the suitable conditions necessary around the sheep barn or shed to ensure full success to the farm flock.

The Sheep Barn

If a new site has to be made for the accommodation of the flock, choose, if possible, high ground and well drained for the building and yard. The yard must be of such a character that it will dry up quickly after rain or thaw. A sheep barn, so long as it is waterproof, dry and roomy, need not be expensive. There are on many farms to-day, buildings and sheds that are not serving any real purpose that could be readily fixed up to shelter the ewes during winter and lambing time. To arrive at the size of the building necessary for the number of sheep on the farm, it can be calculated from the basis of giving 12 to 15 square feet of floor space to each animal. Thus a building 25 feet long by 12 feet broad has an area of 300 square feet floor space, and to give each animal 12 to 15 square feet floor space, the building would accommodate 25 to 30 sheep.

In remodeling an old building, the first duty is to see that its surroundings and floor are well drained and that it can be well appointed with windows to admit the sunshine. If the boards that make up the walls of the old building are open and liable to make the place drafty they can be lapped over with cheap lumber in a way to make it comfortable. If possible the front should face the South, with a large commodious yard on the Southern side. The floor of the building should be well drained, under-drained if at all possible and finished wtih cement or clay if situation is perfectly dry. If it is to be made of clay, the soil to the depth of five or six inches should be cleared away, and its place filled with broken stone or gravel, then the clay may be laid on and firmly packed. When the situation is naturally dry, the clay floor will be found a very comfortable one.

The Barn's Equipment

In no case is it advisable to have a pen larger than will accommodate 20 or at the most 25 ewes. If a farmer has a flock of 30 or even 25 ewes he will find it more profitable to arrange them into two pens. The pens for fattening lambs should be made even less in size than ewe pens. When sheep, that are in for fattening, are arranged in pens of fewer animals in each pen, they will come along faster toward finishing for market, and will economize feed better than when herded in larger numbers.

The lambing pen should be fixed with a number of movable partitions, and each ewe as she lambs should be given a pen to herself for a week or so. Small pens or creeps for the young lambs should also be arranged so that young lambs may be trained to eat a little extra feed. These pens should be so arranged that the lambs can enter them at any time. The doorway to the lamb creep must be made as small as will keep the ewes from entering.

Doorways, both outside and inside of the sheep barn, must be made wide. Narrow doors are apt to hurt the in-lamb ewes when they may chance to be hurried or eager at feeding time. The lower half of all sheep doors should be divided in two, and made so that they can swing either way.

All feed racks must be on a level with the body of the sheep. If hay is arranged above their heads, the sheep will fill their fleeces with seeds and other foreign matter that deteriorates the value of the wool. The racks should be made to give at least one foot of feeding space to each sheep. It will also be found to be of advantage to have the feed rack movable. A feed rack should not be made of larger size than will accommodate 20 sheep. The top part of the rack is arranged to hold the hay or roughage, and the lower part fixed so that the grain feed can be served, being a box extending the whole length of the rack. This feed rack is made in two parts, the part that holds the hay can be separated from the box or grain feeding arrangement. The accompanying plan and elevation of the feed rack for sheep will give a better idea as to its construction. The rack shown is 10 feet long, which will accommodate at feeding time about 20 sheep if they are of small or moderate size, but only 15 to 18 ewes when heavy with lambs. The feed rack should be made so that it can be carried to the ward or field and doors of sheep pen arranged to give ti free and ready passage when being moved.

Never forget to have a watering trough; sheep must get water in the winter time. There is more failure due to this neglect than many farmers ever realize. The severe winters of Canada make this duty rather difficult, but some way must be found to overcome it. Watering troughs must be kept clean; as high as the sheep so that they will not dirty the water, and made of material that will not go to pieces, if by any chance they should get frozen.

PREPARING FOR HARVESTING AND THRESHING

At harvesting and threshing time nothing should be allowed to interrupt the work of getting the grain into the granaries. Preparedness is half the battle.

When a decision has been arrived upon as to the amount of grain to be sown, order the binder twine, allowing from three to four pounds per acre.

Overhaul the binders thoroughly, tighten all nuts, see that knotter and carrier, etc., are all in good working order and oil thoroughly.

When using the binder try to deposit the sheaves in straight lines. This will greatly reduce the time and labour in stooking and subsequent loading of waggons whether it be by hand or sheaf loader.

Repair waggon-racks, boxes and sheaf loaders.

The engine wants overhauling. Secure all fittings and tighten the nuts, renew the batteries if they do not test high enough and overhaul the wiring and spark plugs. Lay in an adequate supply of gasoline and lubricating oils. See that the belt is in good order and, if necessary, oil it and apply resin to prevent slipping.

The separator, to produce a clean sample of grain, must be in good working order, so clean it thoroughly, remove all tufts of beards and chaff so that there will be an even distribution and movement of grain over the sieves. See that the fan is working properly. Have the knives sharpened so that each sheaf may be cut properly. Tighten all nuts and fit the belts and lubricate all the bearings.

Plan to have as few settings of the separator as possible and off the fields to prevent spreading weed seeds.

Where the threshing is done by several settings a large patch of weeds follows at each place and it has been estimated that from three to five bushels of grain are lost. This loss, however, may be greatly lessened by using a canvas under the feeder.

A farmer who does not possess a threshing outfit of his own would do well to stack his grain, for then it will not be at the mercy of the weather should threshing be delayed.

W. H. GISBON,
Superintendent, Experimental Farm,
Indian Head, Sask.

ROGUEING OF FIELDS OF GRAIN

The verb "to rogue", meaning to remove foreign or undesirable types, has not yet come into general usage and the operation to which it refers is perhaps still less known. The high standard of purity set for the seed grain disposed of from the Dominion Experimental Farms makes it sometimes necessary to rogue quite large fields, even up to twenty or twenty-five acres in extent, but such an extensive operation is not advisable for ordinary farmers or seed growers. Nevertheless, even in these times when th cost of labour is so high, many farmers who expect to sell part or all of their grain crop for seed purposes, cannot afford to neglect altogether the rogueing of some of their smaller fields. In the threshed grain, it is practically impossible to separate barley from wheat and quite impossible to separate barley from oats. In a field of wheat or oats, however, when the barley has headed out, it is a simple matter to remove all the plants, provided, of course, the seed sown was not very seriously mixed.

If the principal fields which the farmer is growing are too large to be rogued, as will generally be the case, the smaller, multiplying fields (which should usually consist of only about one or two acres each) should be gone through carefully two or three times at intervals of a week or more, between heading and harvest, in order to remove all plants of other kinds of grain and any abnormal plants observed of the variety which was sown.

If the seed used by the farmer was pure as to variety, there is usually no need to attempt any form of selection. Any very unusual or peculiar heads which are observed should be removed; in other words, the grower should devote his attention to selecting out and rejecting everything abnormal found in his field. This is a much more rapid and, in some ways, even a better process than the laborious plan of picking out the seed which is to be retained.

By rogueing every year the special, small, multiplying fields of pure seed, which every grower should have, much time and waste of good seed can be avoided when cleaning the threshed crop in the fanning mill, and the higher degree of purity of the seed grain which the grower will be able to offer for sale will enable him to command a higher price.

The hand picking of a few bushels of seed grain in the winter months is desirable but this operation cannot altogether do away with the necessity for very careful inspection and occasional rogueing of the smaller fields in midsummer.

CHAS. E. SAUNDERS,
Dominion Cerealist.

In these times when there is a marked scarcity of male labor, and production of foodstuffs is so much called for, there is no more advantageous and healthful manner in which women and children can be employed than in the care of poultry.

Buttermilk is equal to skim milk for feeding hogs, while whey is half as valuable. Whey, being low in protein, is not well suited for young pigs and should be fed to older animals.

What Will You Do For Help?

FARM help is scarce, but this condition can be relieved to a marked degree by using machines that accomplish more work in a given time with less man power.

Why should the farmer cling to horses—a slow, expensive means of power—when every other business is adopting the truck and thereby reducing the cost of hauling, speeding up deliveries, and saving for human needs the food that the horses would otherwise consume?

The motor driven truck can work constantly at maximum load under the burning summer sun, or in the coldest weather. Unlike the horse it needs no rests while working, it eats only while in actual use, and when the day's work is done it requires very little attention, and leaves you free for other "Chores" about the place. Then, it can be housed in one-quarter the space of the horses, wagon and harness it replaces.

It is a mistaken idea that a truck is useful only for driving upon paved roads. The Ford can be driven all over the farm, and used for hauling grain, potatoes, fruit, roots, fertilizer, wood, stock, milk or any other product. The speed it travels, the time it saves, and its low upkeep cost appeal very strongly to all users of the Ford Truck. If you need help, order your Ford One Ton Truck today.

BREEDING

Veterinary obstetrics deals with the care of domestic animals during pregnancy, the birth of their young, and the treatment of the young after birth. Perhaps no phase of veterinary practice is so little understood by farmers and stockmen generally, nor one which a little knowledge and practice are productive of such good results. The period of heat varies in different animals about as follows:

Mare, once in three weeks.
Cow, once in three weeks.
Ewe, once in 16 days.
Sow, once in three weeks.
Bitch, once in six months.

The above periods are the average time that elapses from one period of heat to another. The milk secretion, if the animal is giving milk, is usually lessened during the heat period.

Two Cents a Word.

This department is one of the most valuable in the MARITIME FARMER. At a cost of only 2 cents a word, you can advertise anything you wish to buy, sell or exchange. The aderess must be counted as part of the advertisement and each initial or a number counts as one word. Cash must accompany eacb order and advertisement must have address on. as we cannot forward replies sent to this office. Copy must be received not later than Friday before the date of issue, which will always be found on the editorial page of the proceeding issle. No black faced type or display of any kind will be allowed under this head, thus making a small add as noticeable as a large one. The rate for this column is 2 cents a word, each insertion. MARITIME FARMER, Sussex N. B.

RIGHT WAY TO MILK

The right way to milk is to grasp the teat firmly in the whole hand far enough up that the fingers will not get wet when the milk begins to flow. Lift the hand, opening at the same time that the hold on the teat quite loose. Beginning with the thumb give a gentle pressure or squeeze on the teat, causing the pressure to come all the way down the teat. With a little practice this becomes habit. To milk cross-handed is probably the best way as one has more room, that is milk the right front and left hind teat at the same time. The good milker is on the lookout for a kick from the most gentle cow.

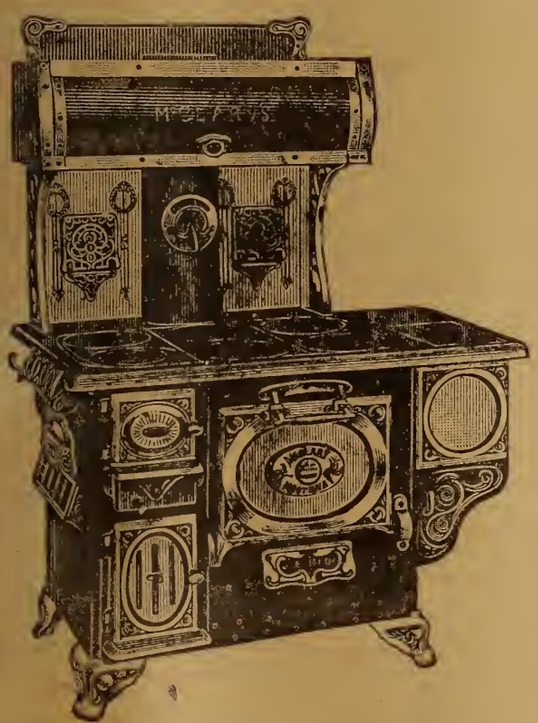
The Four-Way Range Test

1. Ease of Management
2. Economy of Fuel
3. Performance
4. Durability



By these four vital range tests the Kootenay Range is made and sold.

When you buy a range be sure it will stand up to these tests.

The Kootenay system of dampers, checks and drafts is so simple that heat control is literally at your finger tips.

The duplex grates work so easily you hardly notice the effort of operating them.

The burnished steel-like top and the nickelled oven reduce cleaning to a mere dust-cloth operation—these all make the Kootenay easy of management.

The wide, deep fire-box, with ample vents for oxygen, for complete combustion, thus extracting all the heat from the fuel; the quick distribution of the heat to its work; the complete control of the heat—all these save fuel—make the fuel economy.

And the roomy, sanitary oven encased in a complete insulated envelope of heat; the tell-tale thermometer that indicates the exact condition of the oven, and again, the easy, thorough heat control by which you make the heat do exactly what you want it to do, when you waht it and where you want it—those are the tests for performance.

Also many years of use have proven that the Kootenay lasts a life time with ordinary care. It is strong where it should be strong, and scientific construction, with minute care in fitting, make it immune from cracking and breaking so common in old style ranges. Those are the tests by which McClary's ask you to judge and by which to buy.

"Service in the Kitchen"—Booklet Free

These are only a few of many features of the Kootenay Range described in a beautiful little booklet, "Service in the Kitchen," which will be mailed free on request. It tells all a woman wants to know about a range before she buys it.

CONSERVING MOISTURE FOR 1919 CROP

Moisture is one of the main controlling factors in crop production in the prairie provinces.

Three methods of conserving moisture are:

First, to have the ground in such a condition that the rainfall will soak down and not run off.

Second, to keep the surface of the soil sufficiently fine and loose that the upward movement of the water is checked two or three inches from the surface and held there.

The third method of conserving moisture is to destroy all weed plants on cultivated ground.

Most farmers summer-till a part of their farm with two objects in view, to store up moisture and destroy the weeds. Experiments on the Scott Station have shown that early plowed summer-fallow will store up more moisture and give heavier crops the succeeding year than late plowed fallows. Plowing the midle of May has given three and two thirds bushels more wheat per acre than plowing in July. June plowing has given two and two-thirds bushels more than July plowing. This increased yield from early plowing is due to not only storing more moisture, but to less loss of moisture from weed plants, that grow up on the late fallows.

It is sometimes thought that plowing down a crop of weeds will have manurial benefits. Experiments conducted have shown that there is not only a loss of moisture due to the weeds using it, but it is difficult to cover the weeds and make them decay in a reasonable time. Then, too, the ground is left in a more open condition, permitting drying out. Experiments at the Scott Station have shown that plowing down green crops such as peas and vetches does not give as good returns as does incorporating barn-yard manure into the soil.

Early plowed summer-fallows, well cultivated with the duck-foot cultivator will mean an increase in yield, and the frequency with which the land is summer-fallowed and the number of weeds present will be determining factors in regulating the amount of cultivation necessary.

It might be pointed out that where summer-fallowing alternate years is practiced, and there is a reasonable amount of moisture, the land will not stand the same amount of cultivation that land will that is only summer-fallowed once in three or four years. Especially is this true in the northern districts where early autumn frosts prevail.—Experimental Farm Note.

ELEVEN MILLION DOLLARS PER ACRE

There are eleven mililons dollars worth of nitrogen, the most important plant food, in the air over each acre. There are two ways of tapping this wonderful source of wealth. One is by the use of certain expensive machinery which can only be run successfully where cheap power is available. The other method is by raising certain bacteria that can take this nitrogen from the air and put it in the soil in a condition that the plant can use. These bacteria live on the roots of alfalfa, clover, peas beans and the other plants of this family. So that it is necessary to grow these crops if one wants to raise the bacteria that have the power of converting the wonderful source of wealth in the air into available plant food in the soil. The alfalfa, clover, peas and beans, etc., also produce the most nourishing foods for man and beast.

PEAT AS A FERTILIZER

Some 3,000 acres of "river bottom" peat in Illinois are being transformed into fertilizer with good results. The peat is excavated by a dredge and is left lying on the banks of the small canal to dry out partially for a day or two. It is then hauled to the mill, placed in a compost pile under a shed, and allowed to cure for a week or ten days. It is next fed into a dryer in the form of a huge six-foot revolving cylinder heated to a temperature of 1,700 degrees Fahrenheit. About thirty minutes are required to remove the last vestige of moisture from the peat, after which it is ground and screened to 36 mesh. After being ground it is in the form of a dark brown powder, without odor and so clean that it may be handled without causing the slightest smut or stain.

In addition to its value as a fertilizer it has been found that the peat in this form also possesses considerable merit when used as an ingredient in the composition of feed mixtures for cattle, particularly in the case of molasses mixed feeds, such as barley, wheat bran, screenings, ground corn and oats, to which molasses is added. Besides possessing nutritive (?) qualitie sof its own, the peat, being a good absorbent, prevents the other materials from being sticky as would be the case if no peat were used. The peat acts on the rough acid in the molasses, so that cattle when on full feed do not scour so readily. Experiments made with such a amixed food show that ctatle fed on it have better appetites and take on fat more rapidly, because, beiing in better condition, they eat more feed than they otherwise would.

BROKEN GLASS

When glass is broken do not try to pick up the little pieces with the fingers, but lay a wet woolen cloth on the floor where the fragments are and pat it. The tiny particles will adhere to the damp cloth, which may then be burned.

Sheep on Every Hill Side in New Brunswick

The New Brunswick Government through the Department of Agriculture has arranged with the Chartered Banks to help the Farmers—where assistance is needed—to buy Sheep.

The Department will not only arrange to buy sheep **FOR** the Farmers, but will also buy good breeders **FROM** the Farmers—in other words, this branch of the Agricultural Department **WILL SUPERVISE ALL PURCHASES AND SALES OF SHEEP.**

CREDIT FOR THE PURCHASE OF SHEEP

Every bona fide farmer who wishes to purchase sheep for breeding purposes and cannot pay cash may secure twelve months' credit for two-thirds of the purchase price. GO TO THE MANAGER OF THE CHARTERED BANK IN YOUR COMMUNITY AND PLACE YOUR ORDER FOR THE NUMBER OF SHEEP REQUIRED, ACCOMPANIED WITH A CASH PAYMENT OF $3.00 PER HEAD ON GRADES AND $10.00 PER HEAD ON PURE-BREDS. The Manager will forward the order to the Department of Agriculture; the Department will purchase the sheep and deliver them to your nearest railway station. The balance of the purchase price can be paid as follows: Two-thirds, or about $10.00 per head, by a twelve months' note, and a cash payment of about $2.00 per head on grade sheep.

Under the credit system not more than 21 sheep can be secured by any one farmer.

Any farmer who wishes to secure a greater number and cannot purchase locally can be supplied by the Department of Agriculture for cash.

PRICES

FIRST QUALITY stock only will be secured.

All sheep will be carefully inspected before purchasing.

Mature sheep are hard to obtain, therefore ewe lambs will form the major portion of the stock distributed.

Prices will range from $13.00 to $15.00, according to size and quality, delivered at the nearest railway station.

The Department has not entered upon this as a commercial transaction—THE SHEEP WILL BE PURCHASED AS CHEAPLY AS POSSIBLE AND RE-SOLD FOR COST PRICE PLUS TRANSPORTATION AND HANDLING CHARGES.

PURE BRED RAMS

The Department is now purchasing pure bred lamb and shearing rams.

The lamb rams will cost from $30.00 to $40.00 and the shearlings $35.00 to $50.00 each.

Exceptional individuals will cost from $50.00 to $60.00 each.

THE RAMS HAVE BEEN SELECTED FROM RELIABLE BREEDERS IN THE MARITIME PROVINCES, QUEBEC AND ONTARIO.

SUITABILITY OF NEW BRUNSWICK FARMS FOR SHEEP PRODUCTION

The hilly country makes ideal conditions for sheep pasturage. Hay, roots and oats are the staple crops—they are likewise the staple sheep foods also.

THE WOOL PRODUCED IN THE MARITIME PROVINCES IS THE FINEST QUALITY IN CANADA AND BRINGS THE HIGHEST PRICES. MARITIME LAMB AND MUTTON CANNOT BE SURPASSED.

The system of farming followed in New Brunswick makes the keeping of a flock of sheep easy and very profitable.

THE FUTURE

H. S. Arkell, Dominion Live Stock Commissioner, states: "That sheep products have no doubt reached their maximum price, but that he cannot see any reason for a material decline in the price for at least ten years."

Unwashed wool is worth from 70c. to 80c. per pound, according to grade. Good lambs from $10.00 to $13.00 each. Under careful management the first clip of wool and the first crop of lambs will pay for the foundation stock.

If possible, purchase locally.

Secure foundation stock from your neighbors immediately if available—NOT ONE EWE LAMB SUITABLE FOR BREEDING SHOULD BE SLAUGHTERED THIS YEAR.

PROCEDURE TO PROCURE SHEEP

IF YOU CANNOT PURCHASE LOCALLY, PLACE YOUR ORDER IMMEDIATELY WITH YOUR LOCAL BANK MANAGER; HE WILL FORWARD IT TO THE DEPARTMENT OF AGRICULTURE, FREDERICTON. Unless orders are given it will be impossible to secure in time to make delivery before winter sets in.

This is a business proposition—think it over—decide and see your Banker.

For further information apply to THOS. HETHERINGTON, Livestock Superintendent, Department of Agriculture, Fredericton.

J. F. TWEEDDALE,
Minister of Agriculture.

A MESSAGE

FROM

THE AGRICULTURAL COLLEGE, TRURO, N. S.

TO

YOUNG FARMERS WHO CANNOT GO TO WAR

The war has established the value of Scientific Training in every pursuit of life. More than that it has made the nations realize the Fundamental value of Agriculture. At its close, there will be a demand for trained farmers on the farm and in professional life exceeding all previous demands.

Get ready to render your best service to your country by taking a course at the College of Agriculture during the fall and winter months. To meet labor conditions, the college will not open until November 5th and will close April 10th.

The course lasts two years at the conclusion of which students are awarded the Associate Diploma of the College. Graduates may enter, without examination, the third year at any Canadian Agricultural College and obtain the B. S. A. degree in two years. Previous gradutaes have from year to year stood at the head of their classes at Guelph and McDonald.

Instruction is given in Agriculture, Horticulture, Dairying, Veterinary Science, Chemistry, Botany, etc., as well as in English, Mathamatics, Bookkeeping, etc. Write about special practical course this fall in Farm Tractors. You can come to Truro and learn tractor operation under practical farm conditions.

FOR CALENDAR GIVING FULL INFORMATION WRITE

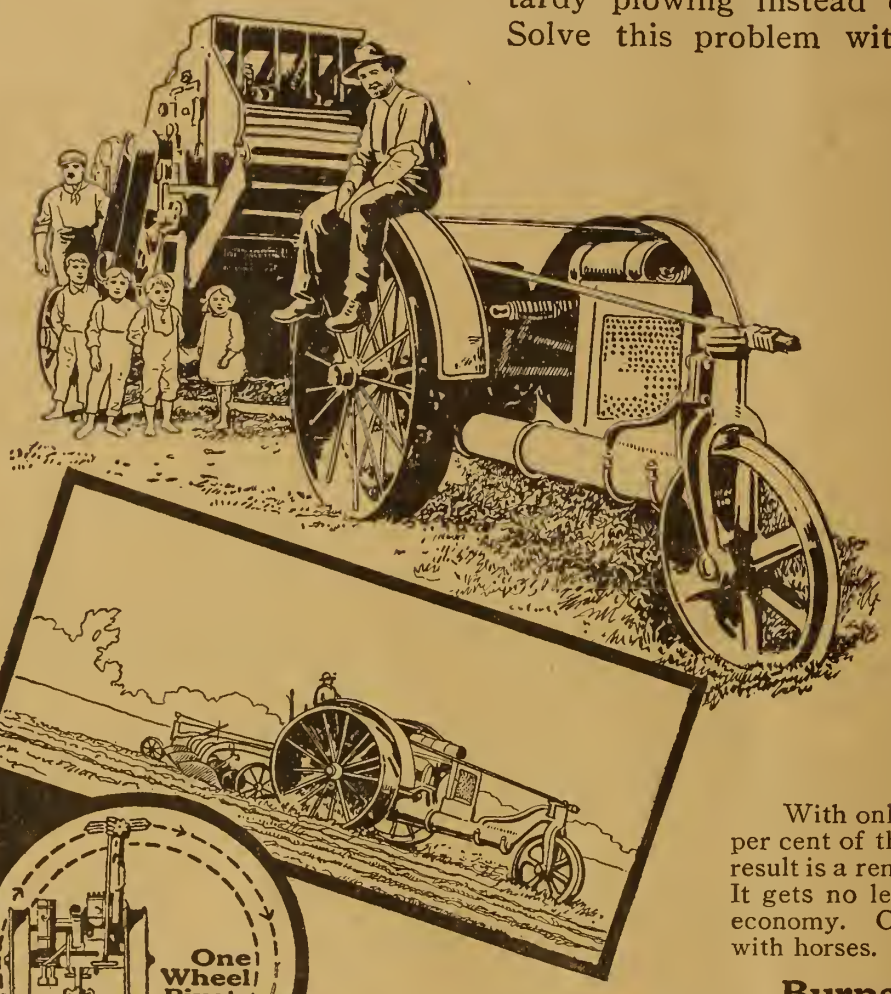
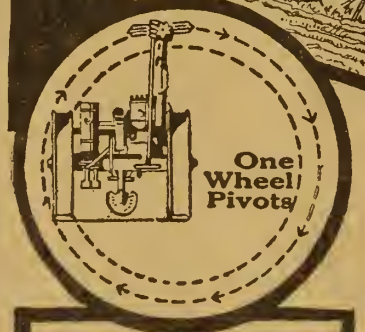
Taking the Risks Out of Farming

LOOK back on the opportunities lost through late plowing, seeding or harvesting. Does it pay? Many a season you may have had to do this work before ground or crop was ready. The last part of this at best was delayed until late. With, say a 25 acre tract to plow, twenty days was required—of which ten were devoted to tardy plowing instead of sowing. Of course it doesn't pay: Solve this problem with the





TURNS IN ITS TRACKS
Means running furrows up to the fences, short turning with the binder, or hauling around the yard. Self guiding in the furrow.

Happy Farmer

12 h.p. at Draw Bar **Tractor** Model F 24 h. p. on Belt Work

Plowing is the big test. Happy Farmer with one man actually does the work that would need three men with three teams of three or four horses each to do. It speeds up plowing and every other kind of work—it pays.

Happy Farmer is so light—only 3700 lbs—that it makes no more impression per square inch on soft ground than horses hoofs, yet it will pull three 14-inch bottoms at an average depth of eight inches.

With only 3700 pounds of weight to propel along and 88 per cent of the weight carried by the big tractor wheels, the result is a remarkable combination of power with light weight. It gets no less than 2000 lbs. draw bar pull. That means economy. Compare it with the four wheel heavy type or with horses.

Burns Kerosene

Happy Farmer Engine burns cheap coal oil, available everywhere. Kerosene means more power at lower cost, providing the engine is a *real* kerosene engine. Happy Farmer *is not adapted* but designed expressly for kerosene. This fuel must reach the combustion chamber hot; our special Carburetor is placed right on the end of the cylinders; the long intake manifold is eliminated, condensation cannot occur, this means the most perfect kerosene burning motor ever invented.

Happy Farmer turns in its tracks, plows up the fences, no unplowed corners to finish with the team, turns sharp corners, with mower or binder, gets in and out tight corners with manure spreader etc. It turns either to right or to left—goes anywhere a horse-team can go. What could be handier?

Happy Farmer just bristles with interesting points of efficiency and economy of service year after year. You should know them. Write for illustrated literature today.

MY LADY'S PERSIAN LAMB

There are probably few people in Canada who have ever given a thought as to whence the beautiful Persian Lamb fur, that ladies so much affect for their outdoor garments, is derived. In 1909, according to a pamphlet issued by the Live Stock Branch of the Department of Agriculture, at Ottawa, the first importation of Karakule sheep was brought into America, with the object of producing on this side of the water what is known to the trade as Persian lamb, Broadtail, and Astrakhan furs. This first importation consisted of fifteen head, ten ewes and five rams. Other importations to the United States followed in 1913 and 1914, with the result that during this time some fifty-four Karakules were imported, the majority of which were rams, the purpose being to mate these rams with the domestic sheep. It was from these importations to the United States that the first Karakule sheep to arrive in Canada were obtained, when in the latter part of 1913 flocks were established in Nova Scotia and Prince Edward Island. The following year other importations were made and several flocks were established in Nova Scotia, New Brunswick, and Alberta. At the present time there are between five and six hundred grade Karakules in Canada produced by crossing Karakule rams with long-wool breeds of sheep and approximately one hundred rams and ewes, either imported or descended from imported stock.

How to Care for Wheat Crops

Timely Suggestions for Handling of New Brunswick's Wheat---With Timely Pointers for Millers and Other Information

By H. Trickey

At this time it would appear that any information with regard to the gristing of wheat would be of great value to those who are personally interested in raising this grain. The idea of the following is therefore to give a few instructive ideas which can be personally applied by the individual. Should any question arise it will be a pleasure to supply information which will lead to the proper solution in the best interests of the farmer.

The people throughout the Maritime Provinces have risen promptly to the occasion, and as a result the wheat crop should without doubt be the largest ever experienced. The need of wheat still remains imperative and without doubt increased production will continue from year to year. This being the cose it will not be amiss, at this time, to point out a number of details which should be universally understood and applied to the crop when same is harvested.

There is apparently no reason why the Maritime Provinces may not turn out as large and fat a berry of wheat as can be produced anywhere. The texture of the berry may be somewhat softer than that produced in Western Canada wheat and the tendency to moisture somewhat more pronounced. There however, can be no doubt that with ordinary care, a very fine quality of flour may be produced. Co-operation with the miller will certainly tend towards giving the greatest satisfaction to all.

In the first instance let us all remember that this country is at war. The fact has been given repitition until we may be inclined to accept it as an incident and overlook it as an essential. Our Allies require wheat and flour and we as a producing country must do our share to supply it. In order to supply more flour for Europe, we must accept a condition of using less ourselves.

Granted that in the past the wheat berry was separated into its three separate component parts—the outside skin, Bran; the inside skin, Middlings; the heart of the berry, Flour; each part consisting of itself carefully separated. To-day it becomes essentially necessary to increase the percentage of flour extraction and in order to do this it is obvious that a fraction of middlings be introduced into the flour. In other words the human being must be given more of the actual body of the wheat berry, the animal as a consequence will get a modicum less middlings.

One thing immediately must become apparent. The flour will darken perceptibly in color, in-as-much as the new element introduced is not so white. Authorities are divided about evenly as to whether this process increases or decreases the food value to the consumer. This question 'pro' and 'con' leaves a situation from which it is emminently fair to assume the actual food value is equal. This being the case we actually benefit others without affecting ourselves; this notwithstanding we should be willing to sacrifice much if necessary. The question of color might therefore well be eliminated and we should accustom ourselves to a condition which will affect the appearance of our neighbor's loaf equally with our own.

Having established a flour basis let us now look at the several ways the farmer may effect the quality of his own flour; always remembering that the miller makes flour according to certain rigid laws laid down by the Canada Food Board. Your miller is positively required to give a definite extraction of flour from a given quantity of wheat. This is not a case of what he can do, nor what the owner of grain would like him to do. Either he lives up to the law or he cannot grist the grain. Nor can any other miller do otherwise.

It would seem desirable that the texture of the flour be kept as fine as possible, that the proper amount of flour be extracted from the berry and that the color be as reasonably white a spossible. In order to secure this result the wheat must be in reasonable condition. It must be reasonably free from foreign matter. It must be of a fine average quality and last but not least, it must be dry. By this it is not implied that it be bone dry, but rather that it be fairly tempered—always remembering that it is better to be slightly over than under dry. Much wheat has appeared at the mill too wet to be floure dat all, not to mention being properly floured.

Several ways of drying wheat are practiced throughout the country. These vary according to climatic conditions in individual sections. Where little rain is experienced, a very fine practice is to allow the grain to remain out in the field a reasonable time. Pile the sheaves in stooks of about six with two extra ones on top to shed any rain which may fall, and in case of a rain do not rush the damp grain into the barn, but see that it has a chance to dry out thoroughly in the air. Nature practices a tempering process that is admirable. However, this is largely impossible to the proper extent and it is therefore only advised where weather precedent would warrant it.

Air is the one best dryer and often by adequate bin construction and placing, the proper temper is secured. In this connection it may be pointed out that a certain amount of moving would not be amiss. Be sure the bin is in a dry place and that a little circulation of dry air is desirable. Certainly be positive that wheat is not exposed to dampness or wet currents of air. The place of storage must be clean and free from exposuie to mustiness or foreign influence of detrimental nature.

When all efforts as above have been insufficient to secure a good drg grain, it is always possible to place a number of filled bags with in the warm air influence of a stove. The trip to the mill may be anticipated a sufficient length of time to secure adequate treatment. The fire probably would be there anyway and the little exertion necessary will be amply repaid in your flouring results. Several cases are known where the grain is stored loosely in the garret of the house and this is a satisfactory arrangement, where the quantity is not too great.

The miller can install machinery to dry your grain, but it is reasonably certain to expect he does not possess it now. It costs money to buy and operate this machinery and of course he would have to make a charge to cover himself. Also the drying takes time and it is desirable that you secure the return of your product as promptly as possible. All things considered, the simple application of common sense to your individual problem will secure the proper results to please both yourself and the miller, who really has just as many problems of his own to work out as you have.

The dryness of the grain materially will affect the texture of the flour. When wet the gluton in the grain is more or less pasty. It sticks to the bran and shorts, it adheres to the machinery and helps clog the elevators; you loose weight and the miller looses his temper. The two skins themselves are exceedingly tough and fibrous, and that part of the shorts which enters into the flour is coarser and tougher, also darker. The flour itself passes through the silks more slowly and tends to clog up. Where the grain is damp when milled, the resultant flour is also damp and when stored in barrels it is always much more likely to get musty. If you want good flour and more flour it would therefore appear that it is absolutely necessary that you treat your wheat properly.

It stands to reason that if foreign grain or matter is allowed to remain when gristing, that this will materially affect the flour. It is therefore desirable that the wheat be cleaned as much as possible, and kept clean and free from foreign matter. One may be surprised to know that such little things as hammers, screw-drivers, pieces of iron, stones and even ten dollar gold pieces are not strangers to the miller. Needless to say some of the above would be of more value elsewhere than in the wheat sack, and one would expect the owner of the gold to be rather careless with such incidentals as other kinds of grain, kept reasonably close to the wheat bin.

Just a little Buckwheat mixture will secure for the farmer a flour which resembles a buckwheat flour more closely than a wheat flour. Just a little Oats will secure for the miller a nice crop of oat hulls in his silks, which will materially affect the flour you get in return. Just a few lumps of earth in the grain will help to darken the flour, and earth is certainly of more value in raising grain than in nourishing the human body.

The cleaning of grain is a matter that has been perfectly solved long since and it would hardly seem worth while going into details at this time. One point might be worth while mentioning which touches the subject in a general way—where individually the problem is too small to work out economically, there is always the recourse to COMMUNITY CLEANING. It pays to have standardized clean wheat for one great reason, profitable returns. Example, with ten bushels of low grade wheat mixed in with twenty bushels high grade you would receive the low grade price on the full thirty bushels unless cleaned and graded. The difference in the price paid for the two qualities when properly separated and excess received on the twenty bushels high standard, will much more than pay for the cost of this cleaning. This is very important in selling grain, but it is of paramount importance in carrying forward seed heat. We know of no place where the farmer can gain as big a reward from as small an exertion as in eliminating the weeds from his seed grain. Let the grain be clean and of high standard quality and the resultant crop or grist will show class as surely as the blooded beast will develop quality in offspring.

Picture for the negligent farmer the hurt feeling and cheated expression, when he hears that his more careful neighbor has received more money for his wheat. Each one brought the condition on themselves. It is probable that wheat will appear for gristing which should really be ground on the chopper for pig feed, rather than the endeavor made to have the miller make flour for the family table, the successful man will therefore control his crop and not let his crop control him; this may sound big but it is really nothing but the application of a little common sense with a very little extra energy. You can control the contents of the package the merchant gives you for your money and just as surely you can control the return the

(Continued on page 768)

Feed Situation in Maritime Provinces

As in Other Parts of Canada it is Acute--Maritime Farmer has Already Distributed Hundreds of Tons of Feed at Cost

In discussing the feed situation, the Maritime Farmer does not profess to be omnipotent. It is simply recording information, gathered on the ground floor by its representative, who has toured the milling districts and from information furnished from official sources. So, if these present indications are not all verified, and feed is more plentiful than the present outlook would indicate, the only thing established will be that officials are only human and that we will have reason to return thanks for conditions which, just now, are far from promising.

Since our last issue we have had a lot of information on the feed outlook, which demonstrates beyond question that the wise buyer will not pin his faith on an abundant supply of bran and shorts. Sir George E. Foster, Mr. H. B. Thompson, Food Controller for Canada, (whose letter is published elsewhere in this issue) and the live stock branch of the department of agriculture, Ottawa, all agree that mill feeds will be far more scarce this season than last. The first call for wheat will be from the men who are fighting in the trenches. Those of us at home will have to guarantee that supply. In order to get the wheat to the fighting front, it is necessary to ship it in the manner which will call for the use of the smallest possible tonnage of sea-going shipping. The method which insures this economy is shipment of wheat in the berry. Grain can be handled through elevators much more cheaply and more rapidly than flour. Therefore there will be less flour ground in Canada this year and consequently there will be less feed. So a substitute will be necessary.

No Cotton Seed Meal

Then the present indications are there will be no COTTON SEED MEAL. The United States government has not consented to the export of any of that comodity to Canada and the outlook is that licenses for export will not be issued. This leaves oil cake as the only available substitute. This supply is also very limited. The Dominion government has been shipping a quantity at $59.00 per ton f.o.b. New York. Less than three hundred tons of this remains. If you want some, wire the Maritime Farmer, and while it lasts, your Society can have it. Supplies in Canada of oil cake are limited too. However, the Maritime Farmer will endeavor to handle your order if you will send it along.

Molasses Hog Feed	$50.00 " "

What Can Be Substituted

However, there is no reason why anybody should sit down and wring his hands. There are feeds to be procured and good feeds too. Months ago the Maritime Farmer, impressed with the fact that the province of Ontario considered it wise to buy 1,500 cars of feed, looked about for a supply and secured it. The feeds which we are able to offer are made from elevator screenings. For years Canadian screenings sold in the United States and there made into feeds of various kinds and sold without trouble. When the feed situation became so acute, the food controller decided that Canada needed the supply and the export of screenings was prohibited, except under special conditions. This feed is now available. Already the Maritime Farmer has distributed some hundreds of tons through various agricultural societies.

Reports are Favorable

The reports received in regard to the feed are favorable. So far we have only sold Ground Special. This feed has been tested by some of the best feeders in New Brunswick, and they are ordering more of it. The feed was something new on the market and the Maritime Farmer decided to test it thoroughly. Shipments were therefore were made to widely scattered centres and the reports received are encouraging. However, it is not as good a feed as the molasses dairy, which with a protein test of 17 per cent, and 4.5 fat, is a good buy at forty dollars per ton f. o. b. Fort William. The freight rate to the Maritime province points will average under ten dollars per ton. Your nearest station agent will give you the freight rate definitely.

Get Your Orders In

If feeds are desired this year, it is well for you to get your orders placed. Transportation difficulties will not be lessened this winter. The outlook is for even greater inconveniences than prevailed last year. Fuel will be a great problem, particularly if we have another hard winter. Then there have been thousands of skilled railway hands taken for the army. In addition to this there are overseas from Canada and the United States about two million men and their wants must be provided for. By winter another million men will be in France and the strain on the railways of the continent particularly under winter conditions, will be severe. Every railroad to the Maritime Provinces will be congested. Therefore it is wise to get feed and get it now.

Analyses of Feeds

The Maritime Farmer has secured twenty-five mixed cars of feeds at the prices given below. The analysis of the various feeds are given. You know what you want and can make your selection. It may be remarked that probably before you get your order in these twenty-five cars will be disposed of, but we will have others to replace them. These feeds are shipped to you at the manufacturer's prices. He will make the draft on you for the bill. You pay him, not us. The prices are all f.o.b. Fort William. That is to say, you pay the freight and all bank charges, exchange etc. The latter item is not a large one but it is important to remember that you are responsible. You must have your local bank notify us that the draft for the feed will be paid on presentation. We only sell through agricultural organizations and expect all persons receiving feeds to be bona-fide members of the organization handling feeds. Then the buyer must be at the time of buying or become a subscriber to the Maritime Farmer at one dollar per year, payable in advance. This is asking very little for the service we are giving. We think it is the biggest service ever given by a farm paper in Canada.

DON'T YOU THINK, MR. FARMER, IT IS YOUR DUTY TO SUBSCRIBE FOR A PAPER THAT IS DOING FOR THE FARMERS A SERVICE WHICH LAST YEAR SAVED THEM THOUSANDS OF DOLLARS AND WHICH THIS YEAR WILL SAVE THEM TENS OF THOUSANDS OF DOLLARS?

JUST AN EXAMPLE. OIL CAKE IS BEING LANDED BY US AT ABOUT $66 OR $67 PER TON. DEALERS ARE ALREADY ASKING $80 PER TON. DO YOU SEE THE 'OINT?

Factors Which Influence Growth and Development of Dairy Cattle

With the high price for feed in recent years the producer of dairy products has to consider more carefully than ever before how to obtain the largest amount of product at the least cost. The cost of production includes a variety of items, the most important of which are labor, capital investment and feed. The cost of a hundred pounds of milk or a pound of butterfat depends upon (1) the total amount expended to maintain the herd and (2) the amount of product secured.

To a large extent the expenses of maintaining a herd are in the nature of fixed charges that must be met and which are not subject to much reduction by skill in management. The results of skillful management are to be expected mostly in a large production per cow rather than in a decrease in the overhead charges necessary to maintain a herd. There are two factors which largely determine the production per cow in any dairy herd. The first is the adaptation of the cow to the purpose for which she is used, the second is the skill with which she is fed and managed. The question which we have to discuss at this time concerns the first mentioned.

It is not necessary at this time to emphasize the enormous importance of the proper selection of the individual cow, as a factor in economical production. Every agricultural paper, every speaker on dairy subjects, calls it to your attention. Your cow test associations are based upon this same important principle and undertake to assist the members in this effort to eliminate the unprofitable cow. My object at this time is to discuss some questions concerning the raising of dairy heifers with a view of answering the question of better dairy cows.

The problem of raising dairy heifers, involves not only the question of economic feeding but also the equally important question as to the influence of the methods of feeding and raising upon the later value of the animal.

Many of the most thoughtful breeders are raising the question in their own minds and asking if it is possible to follow any method of feeding and management of dairy heifers that will make it more certain that the heifers will be good producers. It is another application of the question as to the relative importance of heredity and environment. Does a good dairy cow or an inferior one derive her special dairy characteristics by inheritance, or is it a result of her treatment from birth to maturity? Is a good dairy cow born that way, or made what she is by her owner?

It is a well known fact that there is considerable difference in practice among cattlemen in regard to the feeding and handling of dairy heifers. We find radically different views on some points. Some hold that a cow should be fresh at a very early age to insure the best development of the milking functions. Others take a directly opposite view and prefer a cow to be quite well matured and state that only in such animals are the milk-producing functions the most highly developed. Some who raise dairy cattle feed their calves only bulky feed and in rather scanty quantities. Others feed largely with grain and grow them as rapidly as possible. Some hold that if a heifer of a dairy breed is allowed to get fat when young she develops a tendency to use her food for body fat all her life rather than to produce milk. Others hold that the dairy qualities of a cow are not influenced in any way by the method of feeding when young and that no harm comes from a heifer being fat. Some desire to develop the largest animals possible for the breed. Others prefer cows medium sized or small for the breed.

Noting the absence of any definite information along these lines the writer several years ago started an extensive experiment for the purpose of obtaining some data that would make it possible to decide to some extent at least whether a good dairy cow is the product of heredity or the result of the method of raising.

Before starting the investigation, questions were sent to a list of 1,000 selected breeders of dairy cattle to obtain their ideas on the subject. The

nature of these questions may be seen from the following examples:

1. How long have you been breeding dairy cattle and how many animals are included in your experience?
2. Do you believe from your experience that a dairy cow may be injured by being allowed to become overfat when young?
3. Are there any feeds that should especially be avoided in this connection?
3. Are there any feeds that should especially be avoided in this connection?
4. How would you proceed if you wished to develop especially large animals?
5. Does heavy feeding when young result in a larger cow or earlier maturity than light feeding?
6. Does your observation indicate that the iberal feeding of roughage while young help to develop a strong digestion.
7. What effect has age at first calving on dairy qualities of the cow when mature?
8. What effect has age at first calving on the dairy form or dairy type of the cow when mature?
9. At what age, on the average, do cows of your herd reach their full size?

Replies were obtained from 301 breeders representing the four leading dairy breeds. Experiments were then started to test some of the most important points, especially the influence of a light as compared with a heavy ration during the growing period and the influence of the age at first calving upon the milking qualities of the cow when mature. In discussing the subject the opinions of the breeders and the results of our investigations covering eight years will be mentioned.

In our experiments we used 42 heifers, all registered. and representing the Holstein, Jersey and Ayrshire breeds. Complete records of feed, weights, measurements of growth and records of milk production were kept for each animal until at least two milking periods were complete. One-half of these animals were raised on wholemilk and givn in addition as heavy a grain ration as they would consume from birth to coming into milk. The other group of 21 were fed skim-milk and hay but no grain at all until after they calved. By this means the one group was grown at the fastest possible rate and made as fat as an abundance of grain would make them, while the other group was never in more than moderate condition and growth was slow.

The results of our experiments showed the most marked effect of the heavy ration was a much more rapid growth. The following shows the comparative size of Holsteins at intervals:

Holsteins

Age	Height	Weight	Height	Weight
6 mo.	41.1	422	38.6	317
12 mo.	46.3	654	42.2	432
18 mo.	49.6	912	45.7	598
24 mo.	51.2	1,110	48.4	731
36 mo.	52.6		50.4	
Mature	53.4	1,260	52.1	1,150

A liberal grain ration not only caused a much more rapid growth during the first two years especially, but this liberal ration resulted in developing animals somewhat larger when mature. The light fed animals grew slower but continued growing longer, so the difference between the groups was partially but never entirely made up. The liberality of the ration when young is then clearly a factor having some influence upon the size of the animal when mature, especially if combined, as will be mentioned later with early calving. The same results were obtained with the other breeds. If you want to make a good advanced registry record with a two-year-old heifer, of course, you must feed her very liberally up to that time, and she is then really as old in development and will give about as much milk as a heifer raised on a ration of roughage when three years old. In other words, the more liberal the ration during the growing period, the earlier the animal reaches maturity.

An interesting fact noted in our work is that cows reach their full height and skeleton growth from two to three years before they are mature in weight. A Holstein cow grows but little in skeleton after four years and none after five years. She gains in weight up to about seven years and at times even longer. A Jersey has nearly her full skeleton growth at 36 months, but may grow a little up to four years, while she increases in weight up to six years and possibly longer.

Our results confirmed the opinion expressed by the breeders consulted regarding th influence of the liberality of th ration upon the rate of growth and the final size reached.

Age of Calving

One-half of our 42 animals calved at an age which would be called early for the breed, about 24 months for Holsteins, 22 months for Jerseys. The other group calved at an average age of three years.

The age at first calving is a factor influencing the size of dairy cows. Contrary to common opinion, pregnancy does not retard the growth of the animal either in weight or skeleton, but producing milk exerts a strong influence in checking growth both in skeleton and weight. Light fed Jerseys calving at an early age showed an average height of 48.5 inches at 30 months, and others on the same ration but calving at 36 months, were at the same age 49.1 inches in height. The difference in weight was even more pronounced. Animals calving at an early age never reach the size they would if calving a year later. The most pronounced results with reference to size may be brought about by a combination of a light ration during the growing period and early calving. A heifer undersized from a poor ration, and calving at a very early age, is almost certain to remain undersized. The combination most favorable for developing the largest animal is a heavy ration when young and late calving. The better her milking ability the more pronounced the effect. As a result of these combinations we were able to develop one Jersey that was 53.4 inches in height and weighed 1,122 pounds when mature, while another was only 47.3 inches in height and weighed 720 pounds at maturity.

Another experiment taught us that a ration extremely low in protein may retard the growth in a heifer in the same manner. That is to say if the growing animal is given a very low protein ration for a long time an undersized animal is to be expected. There is little danger of a heifer suffering from a low mineral matter in the ration and none if a legume hay is fed. Having discussed some of the factors influencing the size of animals it may be well next to raise the question as to the importance of the size of the cow to economical milk production and whether w ewant a large cow or a small one. Is a large animal desirable? In general, those keeping cows to produce dairy products for sale prefer a cow medium to large for the breed. Most breeders have the same preference but some, especially those breeding the smaller breeds, do not favor an animal large for the breed and often look with more favor upon the smaller types. The cows that have made the largest milk and fat records have without exception been large animals for their breed. Prof. Woll has also shown that the highest production is found with cows that are large for the breed to which they belong. The indications are that the stimulation to give large quantities of milk may be inherited entirely independent of size. An undersized cow with a great stimulation to give milk is limited by her capacity to digest feed and cannot compete with a larger cow that has inherited the stimulation to give milk to a high degree and has capacity to handle the feed necessary for high production. From an address by Prof. C. H. Eckles of the Missouri Experiment Station.

Good News for Fertilizer Users!

Agricultural Societies United will Have Acid Phosphate and Nitrate Supply for Next Year---Prices Higher Than in 1917

The directors of the New Brunswick Agricultural Societies United are in the pleasant position that they can announce definitely that a supply of unmixed fertilizer will be available for the year 1919. The orders have been placed for acid phosphate and for nitrates and full particulars, with prices will be mailed to the agricultural societies of the province in the near future.

While the fertilizer situation is acute and caused the directors no small concern for a time, things have been shaping better and there will be nitrates available, in as large quantities as last season, if not an even better supply. The prices are up a little but the advance will not be a serious one. tl may be stated that a few weeks ago the United States government prohibited the use of nitrates for any purpose, other than the manufacture of explosives. This came as a severe blow to the fertilizer dealers, but the N. B. Agricultural Societies United did not sit down and cry about it, but got busy and located nitrates. The other was easy and several thousand tons will be at the disposal of agricultural organizations at cost.

There will also be available in this province at cost, mixed fertilizers 3-6-5. These goods have alerady been tried out in large quantities and are found to be superior. Farmers in Carleton county, who have used them this season, are satisfied that the goods are all right and there will be a good supply at very reasonable prices this year. These goods will be available at cost to agricultural societies and something more definite will be announced a little later.

The directors of the Agricultural Societies United have decided to supply branches of the United Farmers upon the same terms as agricultural societies. The object of the movement is to give service to farmers who will organize. The work is growing and promises to bear greater fruit in the future. Get organized. Await the prices of the N. B. Agricultural Societies United before placing your order.

CARE OF EVERBEARING STRAWBERRIES

The most important treatment for ever-bearing strawberries is thorough cultivation throughout the summer to retain soil moisture. The plants should be given clean cultivation and should be hoed in the rows to keep down all weeds and to maintain a fine dust mulch throughout the growing season. After every rain the ground should be cultivated and hoed to break the soil crust around the plants and to re-establish thoroughly the dust mulch on top.

If the summer is hot and dry, it is advisable to apply between the plants in the row a mulch of old, finely-rotten straw, decomposing leaves or other available material which does not contain weed seeds. This mulch keeps the ground cooler, helps to retain moisture, induces fruitfulness, and keeps the berries free from soil particles. It is not wise to apply this mulch until the weeds in the row have been killed, as it interferes with cultivation. If thorough clean cultivation in a row has been kept up during the spring and early summer, most of the weed seeds will have sprouted and the weeds will have been killed before the mulch is applied upon approach of summer drouth.

Just before cold weather in autumn the entire patch should be mulched with straw, prairie hay or other loose material. Care should be taken to select a mulch which does not contain noxious weed seeds. This mulch should be left on the row until after the main fruiting season the following spring, according to J. C. Whitten, of the University of Missouri College of Agriculture.

SURVEYING NEW BRUNSWICK SOILS

Mr. E. F. Taylor, of the provincial department of agriculture, is engaged in an extensive survey of the soils of New Brunswick. Mr. Taylor is a graduate of Macdonald, and took high honors in soil analysis. His work is something in which this province stood in great need. The task before him is a big one, but it is in competent hands. Mr. Taylor has already covered a lot of ground and his findings should be worth a lot of cold cash to the province. It is worthy of note that Mr. Taylor will be associated with the N. B. Agricultural Societies United and that his services will be available in giving advise as to the fertilization of soils.

MAKE FARM POWER MORE EFFICIENT

Efficient motive power is a most essential factor in increasing agricultural production.

"Since the horse is our main dependent in performing farm work, he is given first consideration. To increase the efficiency of our horse power:

1. Treat the horse kindly and give him the best of care.
2. Water him frequently. It increases his endurance and power.
3. Feed regularly a uniform ration.
4. Feed about one and one-third pounds of grain and one pound of hay for each hundred pounds live weight.
5. Feed heavier for severe work conditions.
6. Allow rest periods occasionally.
7. Watch the horse carefully. Drooping ears, unsteadiness of gait, short and quick breathing, and a sudden ceasing to sweat are danger signals demanding prompt attention.
8. If the horse suffers a heat stroke, remove the harness, protect him from the sun, apply cold to the head—either water or ice—wash out his mouth and nostrils, and sponge his entire body with cold water.
9. Provide as cool a place as possible for the work horse at night.
10. Avoid overspeeding and fretting.
11. Eliminate lice, worms and flies.
12. Groom the work-horse thoroughly.
13. Clean the collar every time it is put on the horse, and keep its bearing surface hard and smooth.
14. If possible, sponge off the work horse, especially where the collar and other parts of the harness have left their marks when he comes in from work. Sponge out his mouth, nose and eyes. Wash his shoulders every night for a few weeks with cold salt water.

Some folks have toughened themselves by being out-of-doors in all sorts of weather; but nobody ever saw a plough, mowing-machine or other farm tool that was made any better by that kind of treatment. It can't be done!

USING PICTURES IN SELLING STOCK

The breeder of the animals that are masterpieces in the livestock world of today is just as much a genius by having produced such splendid animals from the raw material of the scrubs of former years, as the man who carves exquisite works of statuary out of the solid marble blocks. He has even more use for art in his business, for after producing these animals, he must sell them at good prices or his operations will cease. Art is used in more ways than one in showing the prospective buyer the excellence of the animals for sale. The best specimens are fitted and shown at the county and provincial shows. After having bred the very best of animals, it takes unusual ability to be able to pick the best ones from the herd and prepare them so as to show them to the best advantage.

Public sales are made in which the ability of the auctioneer as an oratorical genius is the work of art upon which depends, to a great extent, the success of the sale and ultimate success of the breeder in the business. We sit in rapt attention while a Woods, a Repert, a Duncan, a Harriman or a Gross inspires us to pay unheard of prices for the animals offered. They may do it with inspiring oratory or by using the plain, blunt truth in a forceful way. In any case their ability to sell the animals is in keeping with the work the breeder has done in breeding them and getting them ready.

To get the buyers collected at the sales and to sell animals by mail without the purchaser seeing what is present, we advertise in the good papers that are in line with the business. The ability of a fieldman to describe the animals for sale, in an attractive and accurate way, has a great deal to do with their sale. It is here that art plays its silent work. The ability of the fieldman to draw word pictures that attract the buyer is assisted by the man who makes real pictures that show the animal as nearly as is possible in real life.

A real picture will show in a glance what it takes pages to try to tell in writing. At its best the description cannot show the delicately-proportioned animal as a live object as the picture can. Pictures are indispensable to the display advertisement. They are attractive, and, if properly arranged, they give every advertisement an individuality that is really artistic. And then the last great appeal is made in the catalogue. It owes its attractiveness and ability to command the attention and presence of men from hundreds of miles away to the sale at the appointed time, largely to the pictures used in making it up. It is here that art speaks louder than words of tongue or pen. A real life-like picture, by its silent expression of the animal it represents, wileds a mighty force over the man who looks at it. The appreciative breeder knows something of the real object and is stirred to the depths of his pocketbook.

Cattle papers are running over with pictures that are real works of art. And the cattle industry has gained a momentum in the last few years such as it has not known for 40 years. Art has been one of the most powerful stimulants to this onward rush. It has idealized the perfect animal to a certain extent by minimizing the defects and exaggerating the merits. With these ideal animals in mind and with an intelligent understanding of the laws of advertising, the breeder will be able to produce ideal living animals with as much certainty as the sculptor moulds the plastic clay or hews the solid granite.

The young breeder of today is the veteran breeder of tomorrow, just as the boys of the present will be the men of the future. Every breeder recognizes the value of the beginner and should help and encourage him in every way possible. The older breeders should try to get more young men interested. There is no force that has a stronger tendency to draw recruits to the ranks of the progressive breeders than that of the life-like pictures to be found in the breed papers. The young man or boy, who has been accustomed to seeing ordinary cattle or hogs, often receives an inspiration to breed better animals by looking at these pictures. The pictures build the ideals and ideals inspire one to perfection both in desire and attainment.

Breed papers must be, auctioneers are absolutely essential, and both are doing a great and wonderful work. Art should and will be a great factor in the work of breed promotion when we awake to its real worth and the valuable assistance it can render in this work of advancing the interests of fine stock breeding.

KEEPING STOCK HEALTHY

Better than medicine is the prevention of disease. A few year sago at a state vetreinary conventio na member of the profesion indulged in denunciation of county agricultural agents because the one in his county had instructed his clients how to feed horses, cattle and hogs so as to avoid some of their common digestive ailments. The veterinarian asserted that he could notice a decrease in the number of cases of that kind which he was called to treat. That member of the profession is the exception, however. Another veterinarian in the same county makes it a point to instruct his patrons as to suitable feeding and care. And significant of the success of right-doing the latter veterinarian has four times as large and profitable a practice as his narrow-minded contemporary.

It is every stockman's duty and privilege to keep his stock as healthy as possible. It tis profitable to do so, and at this particular time the national welfare requires the conservation of all farm animals. Everyone whose duty it is to care for cattle, horses, sheep, hogs, or poultry should realize that most of the ills of animals can be traced to improper feeding and careless indifference to their comfort. The skilful feeder seldom has sick or dead stock. It is natural for animals to be healthy and vigorous without drugs. They must have suitable amounts and variety of feel, and they require good water. Those are the prime essentials on which health and vigor depend. If these factors are skilfully handled the factor of sickness will seldom enter the equation.

THE SHEEP KILLING DOG

Old Collie around home seems a peaceful canine. He doesn't look or act like a sheep killer. But every night, over the country, a few hundred old Collies, Towsers, Sheps, and dogs of high esteem at home, useful enough and harmless so far as their owners know, set out on little rampages, and in the morning a sheep owner somewhere finds some of his stock dead or worried. We usually blame dogs kept in town for these depredations. Nearly every town has a dog fancier of some kind whose hobby usually runs to hounds, or if no fancier exists the barber, perhaps keeps a bird dog, or one or nondescript canines simply hang out around the village, miraculously escaping the usual annual clean-up of ownerless pups, and these are supposed to commit most of the ravages caried out against the sheep flocks of the community. They do their share, no doubt, but one of the peculiarities of the sheep-killing dog is that he is not any more apt to be the town hound than the respected and well regarded farm dog. One will develop the killing vice as readily as the other, and will carry on his work with a slyness that makes detection next to impossible. Old Collie, snoring under the kitchen table in the early part of the evening, may be anything but a peaceful and respected canine before dawn. But it would be pretty hard to prove it on him in the morning. Sheep killing is a vice that dogs readily acquire and, having once started, cannot be broken off. Sheep killers hunt usually in pairs or small groups and attack flocks anywhere in their immediate neighborhood or miles away, almost always at night, making it hard to determine just what dogs of the community are the guilty ones. After a dog has killed a few sheeep, the vice becomes a mania, and he not only kills sheep himself but leads other dogs to the work. Few would ever suspect their own dog of killing sheep, the sensible, useful farm dog least of all; but the fact remains that sheep are killed by dogs every day of the year, and so many experiences have been recorded of the dog most highly esteemed proving the worst sheep-killer in the community and the most cunning in obscuring the evidences of his clandestine prowlings, that practically any dog is open to suspicion. The best means of being sure that the innocent looking lod Shep, snoozing in the sun of a warm afternoon, may not be committing depredations on a neighbor's sheep flock in the early hours of the following morning, is to keep him fastened up at night.

* * *

Diversify your farm produce. Do not try to raise all one commodity no matter the price.. The best and most successful of farmers are those who keep something of everything.

The traction era is drawing. The romance of the automobile business bids fair to be duplicated.

Visit a demonstration at Florenceville, Fredericton or Baltimore in September, first and second Tuesdays and Fridays in consecutive order as above mentioned.

GETTING AFTER PROFITEERS

Food Board Records large number of Convictions. Price of Mill Feeds are fixed and userers are liable to Prosecution.

The Maritime Farmer has been receiving complaints from a number of points to the effect that mill feeds are being sold at prices which are in violation of the rules laid down by the Food Controller. All mill feeds are sold under license and the profits on bran and middlings are definitely fixed. Those who violate the law may be prosecuted. The Maritime Farmer is in receipt of a letter from the Food Controller, covering violations, which will be read with interest by buyers of feed.

The letter is as follows:

Ottawa, August 26th, 1918.

In answer to your letter of August 22nd, the Orders of the Canada Food Board have the full effect and force of regular statutes and, as you know, are enforcable in the regular way by the Provincial and Municipal Police. All over Canada this is being done.

Anyone who knows of an infraction of the regulations of the Food Board can inform the Police, and surely it is not asking too much of the farmers, in their own protection, to request that they do this and so help to have the food regulations carried out. If the matter is brought before the Police and is not adjusted by a Magistrate, if we can get specific information, we will at once investigate and take action. In the present edition of The Bulletin, which I enclose herewith, you will find over fifty cases where we have taken after them and fined or closed up.

Unquestionably bran and shorts will be scarcer this year than last as the quantity of milling wheat in Canada is going to be very small, and proportionately there will be a bigger demand for feedstuffs. We wrote fully to the Department of Agriculture for the Province of New Brunswick, on July 30th, dealing with the situation. Some of the provinces in Canada have already taken precautions to ensure a supply of feed for their farmers. I feel that I am right in advising you not to rely much on bran and shorts for the coming winter, but to see what can be done in the concentrated feed line, and it is none too soon to make these necessary arrangements.

I am glad to see that the crop conditions in New Brunswick are reported to be good, and I sinceerly hope that you will have success in harvesting every last pound.

Yours faithfully,
CANADA FOOD BOARD,
Harry W. Thomson,
Chairman.

J. D. McKenna, Esq.,
The Maritime Farmer.
Sussex, N. B.

SHEEP NOTES

Dr. L. H. Price of Moncton believes in the sheep business, also in co-operative marketing of wool. He has given tangible evidence of this by taking five shares in the Canadian Co-operative Wool Growers Limited.

E. W. Spinney of Hartland writes in, "Returns for wool to hand. Very much pleased with result of marketing co-operatively."

Agricultural Society No. 114 has been using pure bred rams of the Down breeds for years. This year twelve members of the Society marketed their wool at the Fredericton warehouse. One-half graded and sold at 81½ cents, one-sixth at 82¾ cents; one-third at 75½ cents.

Urban Haines of Burtt's Corner clipped 18 pounds of wool from a two shear Shrop ram. This is the high water mark for Shropshires.

H. S. Arkell, Dominion Livestock Commissioner says, "No doubt sheep prices have reached their maximum, but that he cannot see any reason for any material decline in the price of sheep products for at least ten years." He should know whereof he speaks.

J. H. King of Sussex is keeping all his Shropshire ewe lambs this year. Confidence in the future alright. Probably J. H. King had something to do with it.

Harding Brothers of Welsford are considering whether the Shrops will pay as well as the Holsteins. Wouldn't be surprised to see Tim bring home some "good un's" from up country.

Burder Goodwin of Baie Verte, N. B., will clean up in Oxfords at the Charlottetown fair. We like to see N. B. breeders bring home the shekels. Burder claims that a cow makes as good a mother as a ewe. One ewe died this year and the old family cow has been drafted. She certainly responded. Probably brought up his best lamb this year.

The Leilbac Sheep Products Company of St. John with a ranch at Devil's Back, Kings County, are stocking up with 100 breeding ewes. They are investing $600.00 in 10 pure bred Shrop ewes and two pure bred Shrop rams. Big money, but they are cut for the best.

Country drovers say "That in those districts where the use of pure bred rams has become general, we find a marked improvement in the mutton qualities of the lambs. This is most marked where rams of the Down breeds have been used."

There will be a scramble for pure bred stud sheep later on. Better get your order in early. The early bird gets the good ram.

Prof. Barton says "A pure bred ram is at least half the flock and if a good one, is a whole lot more than a half."

N. B. farmers should keep an eye on the quality as well as doubling the quantity of sheep in the province. Buy a good ram.

Thomas Tetherington,
Supt. of Livestock.

CARE AND REPAIR OF PLOUGHS

Probably no implement used on the farm receives a greater measure of abuse, or as little attention to its proper care, operation and repair, as the plough. To quote a recent writer on machinery: "The plough is the basic tillage tool, the fundamental farm implement. It is not merely a tool for inverting the furrow slice, but it is the most efficient pulverizer of the soil in use. As the moldboard turns the furow, each particle of soil is forced to slip against the particle adjoining, a process which results in a tilth that no other single operation approaches. The general impression prevails that the plough is a simple tool, requiring but little adjustment and less care. This is far from the truth, however. Without question it is the most complex tool on the farm, in that it requires the greatest skill for adjustments, the grain-binder and the gasoline engine not excepted. More effort has been expended in the slow process of development of this seemingly simple tool than in that of any other impdement on the farm. Careful study of its construction, adjustment, and use will be amply rewarded.

This useful implement should not be allowed to remain in out-of-the-way places subject to deterioration by weather conditions, but should be housed properly when not in use. When laid by, it should be stored in a dry place away from contact with the ground and the bright parts coated with grease to prevent rust. Once the moldboard share and landside have become pitted with rust an efficient job of ploughing cannot be done until the corroded parts again have acquired a polish by use. In overhauling, the following scheme is suggested:—

Repairing a Walking Plough

Share.—If chilled cast iron and badly worn, renew. If steel and badly worn, should be sharpened, bearing at wing three-quarters of an inch for 10-inch bottom to one and a quarter inches for 16-inch bottom; vertical suction one-eighth inch; horizontal suction, one-eighth to one-quarter inch.

Landside.—If badly worn and detachable sole is provided, replace sole, otherwise it will be necessary to renew landside.

Moldboard.—Usually in two parts, shin and moldboard proper. If shin be present and badly worn, renew. See that moldboard is bolted tight to frog.

Barcing.—If loose, tighten up connections.

Handles.—If loose, tighten up bolts so that they are attached rigidly to bottom and see that bracing is tight.

Beam.—If loose, see that bolts to frog are tight.

Gauge Wheel.—Examine bearings and if badly worn replace with new. If plain bearings, do not lubricate. See that gauge-wheel standard is bolted rigidly to beam.

Jointer.—Examine point, if badly worn and if chilled cast iron, renew; if steel, it may be sharpened. See that it is bolted rigidly to the beam.

Rolling Coulter.—Seldom used on hand ploughs but if present examine the coulter-wheel bearing and if badly worn, renew. See that the standard is attached rigidly to the beam.

Fin or Hanging Coulter.—Should be attached rigidly to the beam and sharpened if worn.

Adjustments

Depth of furrow.—Made by raising or lowering the clevis or bridle on end of beam. This also may be regulated slightly by the gauge wheel where wide and frequent variations in soil conditions prevail. The gauge wheel should not be used where the soil conditions are uniform, except in very stony soil, as it increases the draft of the plough. In any case, there should not be excessive bearing pressure on the gauge wheel, the function of this wheel being to prevent ploughing at a greater than the desired depth when passing from a firm and hard soil to one of more friable nature.

Width of furrow.—Made by shifting the hitch on the clevis or bridle to or from land according to whether a greater or less width of furrow slice is desired. In using more than two horses this also may be regulated to some extent by the gauge wheel if this wheel has a standard which may be adjusted to lead to or from lanad.

Handles.—Should be adjusted to suit height of operator.

Jointer.—Should be set so that its point is just above or just back of the point of the share, to run one and a half to two inches deep and slightly to the inside of the shin of the plough.

Coulter.—If used, it should be set in a position similar to the jointer except that it should run about half the depth of the furrow. A rolling coulter does not, however, take the place of a jointer. The functions of the two attachments differ in that the function of the jointer is to turn under a small furrow slice ahead of the furrow proper, so that a smoother job of ploughing results and, that of the rolling coulter to cut tough grass roots and surface trash, so that they may be covered more efficiently by the furrow slice.

Hitch.—The theoretical line of draft originates at a point about two inches from the mold board side of the ship, just above the junction of the shin and moldboard. This line should pass through the hitch at the beam clevis and end at a point midway between the sort tug rings at the hames. Anf variation from this line will influence the ploughing, such as too short or too long traces, short hip straps, etc. If this line be straight and the reins adjusted properly, the plough properly set for depth and width required no effort of the operator is neeeded in guiding, except to steady the plough in a proper running position when obstacles are encountered.

Repairs for Sulky and Gang Ploughs

Wheel bearings.—Take down, clean with cloths saturated with kerosene oil, make adjustments for wear if provided for, and repack with heavy grease before assembling.

Frame.—Examine for loose bolts and connections and take them up.

Landing and lifting levers.—See that all connections are tight and take up lost motion if possible.

Beam and frog.—Examine for loose bolts and connection and tighten if present.

Share.—If worn, replace or sharpen.

Landside.—If worn and has removable sole, replace the sole, otherwise replace the landside.

Coulter.—Rolling coulter usually is used. Examine the bearings and renew if necessary. See that coulter standard is attached rigidly to the beam.

Adjustments

Depth.—Regulated by raising or lowering the bottom, in relation to the frame. Suction as applied to sulky or gang plows is the distance of the back end of the landside from the floor with the point and wing of the share resting on the floor. This is about one-half inch for most ploughs though it may vary for different lengths of landsides.

Width.—Regulated by adjusting the hitch to or from land on the frame. It may be regulated also to some extent by "landing" the front furrow wheels.

Jointer.—If used, it should be set so that its point is just above and just back of the point of the share, to run one-and-a-half to two inches deep and slightly to the landside of the shin of the plough.

Coulter.—Should be set half the depth of the furrow back of the point of the share and slightly to the landside of the shin. If used, in connection with a jointer, it should be set ahead of it.

Wheels.—The land wheel should travel directly to the front of and parallel with the furrows. The front furrow wheel is given a small lead from the land, likewise the erar furrow wheel. The rear furrow wheel should run one or two inches outside the landside of the plough.

Hitch.—In anay wheel plough the load should be carried on the wheels a smuch as possible to reduce the draft. The driver may test this by dismounting while the plough is under way and taking hold of the frame at the front wheel and sliding it sidewise, and doing likewise at the rear furrow wheel. If equal resistance to side motion be encountered it is reasonable to assume that all the load is carried on the wheels. The load may be equalized by raising the point of the hitch or lengthening the traces.

Repairs for Disc Ploughs

The general features of disc ploughs are the same as in other ploughs except that the bottoms are replaced bf disc.

Refer to sulky and gang ploughs and examine:—

Disc bearings.—Take donw, clean with kerosene, replace the worn parts, and assemble with sufficient grease to pack the bearings properly.

Disc.—Sharpen or replace if badly worn.

Scrapers.—See that all connections are tight and if the scrapers are badly worn, renew them.—Farm Implement News.

The advertising columns contain the business news of the country. They are a mine that the buyer will work diligently before he buys. It is up to the seller to get an announcement of his wares where they will attract attention. Hiding one's light under a bushel was condemned in holy writ. It has never become popular, because it is contrary to good business principles.

HORTICULTURE

CONTROL ONION DISEASES WITH EFFECTIVE SPRAYS

There are three insect pests, namely thrips, mangots, and cut worms, which often cause considerable loss to onion growers.

The onion thrips chafes off the epidermis of the leaves, principally at their base, producing yellowish, gray irregular spots on the leaves, later causing the entire leaf to dry up and die. In order to spray onion thrips successfully, high pressure (at least 100 lb.) and a fine mist-like spray which can be directed into the base of the onion leaves are necessary. A gasoline outfit or good hand pump outfit equipped with a long line of hose and extension rod is the most satisfactory type that has been used thus far. The following spray material is very efficient if it comes in actual contact with the insect:—concentrated nicotine sulphate, 5 oz.; whale oil soap, 4 lb.; water, 50 gals. The spray should be applied when the thrips fire appear and the onions are small and easily sprayed. It will probably have to be repeated two or three times at intervals of ten days in order to destroy succeeding generations as they hatch.

The onion fly lays its eggs in the sheath of the onion when the plants are very small. The eggs hatch in about 10 days and the maggots burrow into the bulbs of the onion, causing the loss of the plant. Sometimes whole fields are thus ruined. A second and sometimes a third brood appears later in the season. Field hygiene is especially important in controlling onion maggots. A new method of control devised at the Wisconsin Experiment Station is claimed to give excellent results. This treatment, called the "poison bait spray," destroys the flies which lay the eggs. It is used as follows: as soon as the onion seedlings appear, the first spray should be applied, and it should be repeated at intervals of five days or a week during the period when the flies are present. The spray consists of one ounce of sodium arsenite, 2½ quarts of molasses and 5 gals. of water. The arsenite should be dissolved in boiling water and the molasses added and thoroughly mixed. This bait must be applied, by means of a whisk or broom or of a spray outfit with a coarse nozzle, in large drops along the rows sothat the flies can drink it.

After onions have become infested with maggots, there is nothing that will remedy the difficulty that season, but infected plants should be promptly removed and burned in order to reduce the number of insects that will appear the following season, and then the poisoned bail applied in time to destroy the flies before they can lay their eggs.

Cutworms cut off the young plants at the surface of the ground. They can be controlled by the use of poisoned bait prepared as follows: Mix 50 lbs. of wheat bran or middlings, 2 lbs. of Paris green and 6 finely chopped oranges or lemons. Then add enough cheap molasses and a little water and place the mixture around the plants.

Onion mildew is a most serious disease and may be controlled by spraying with Bordeaux mixture.

GRAFTING

On many farms, the apple orchards might be greatly and permanently improved by grafting some of the trees. In addition to cetrain incidental benefits, there are 3 special purposes which this work can be made to serve. These are as follows:

First: It can be made to prolong the usefulness of trees which, though fairly vigorous, are past middle life and would produce more and better fruit if they were caused to form new heads. This change cannot be made at once, but it may be effected in five or six years with very large trees, or in three or four years with smaller ones. Large orchards have been successfully "renovated" in this way. It is not the ideal method for maintaining an orchard, but it may be the wisest treatment for one that has been neglected. The better practice is to plant at brief intervals and thus have young trees coming into bearing while the mature ones are beginning to fail. Under this method, individual trees will perish, but the orchard as a whole will never grow old.

Second: By means of grafting, new varieties can be introduced without unduly increasing the number of trees in the orchard. When apples are grown for the market, the number of varieties should be small, but when they are grown for the family, there should be a wide range. A few large trees may be grafted with from two to four kinds each. The quantity of any single variety that is grown in this way will be small, but it probably will be sufficient for home use. This method will furnish first-haid information regarding the appearance and quality of applies of several and widely different kinds, and will enable each member of the household to have his or her favorite sort.

Third: Grafting may be used to improve the quality of fruit in orchards for which the varieties were not wisely chosen. Trees which yield fruit of only moderate quality may be made to produce a much finer grade. Then, too, shy bearers may be grafted with more prolific sorts, and varieties of which the fruit is excellent, but the trees are weak, can be grown in more vigorous stocks.

The art of grafting is easily learned. Every boy who works on a farm should master it. He will thereby gain a new interest in the home orchard and form a new attachment for the farm. In every farming section there are experienced men who would cheerfully show any boy in the neighborhood how th work is done; or the art can be learned from books or papers. The first effort should be on an inferior tree. My first work in this line was on an old and large R. I. Greening tree. It was a great many years ago, but I well remember the pleasure it gave me, and my satisfaction with its success.

Largely because of this experience and also because of the possibilities for good that such knowledge brings, I favor giving every farmer boy an opportunity to learn how to graft trees in the apple orchard, and thus become able to benefit himself and others in later years.—J. E. R.

Eureka Potato Digger

Gets the Potatoes and pays for itself in one season. Saves extra help

Potatoes frozen in ground last Fall could have been saved by the Eureka. Works in ground and conditions where other diggers cannot.

The Eureka elevator and duplex shaker provide more separation than other diggers. Large wheels and main gears supply ample power. Special construction avoids frequent breakage and lost time. Growers report digging 150 or more acres without repairs. High clearance over shovel prevents weeds and vines bunching. Has vine-turner attachment.

Specially adapted for use with tractors and for engine attachment.

6-ft. and 7-ft. sizes; several styles.
Prompt shipments from distributing points.

RASPBERRY LEAF CURL SYMPTOMS AND CONTROL

Raspberry leaf curl has been known for some time both under this name, as well as under the name of raspberry yellows. Since the curling of the leaves is the most outstanding feature in connection with the disease, it is preferable to use the term raspberry leaf curl.

The disease affects the leaves and shoots and is often confined to a single bush or part of a bush, some of the shoots being perfectly normal and others with the leaves affected. The affected shoots, instead of producing normal large, broad leaves, bear leaves which are conspicuously small and badly curled downwards. In the early stages this symptom is not so pronounced, and while a small amount of curling may occur then, the disease is more noticeable on account of the yellowing which takes place during the summer because of the unhealthy state of the foliage. Since yellowing of the leaves may be due to a number of other causes, such as wet feet, poor soil, drought, etc., it is best to determine the disease mainly by the leaf curl symptoms.

In the advanced stages, the canes bear no fruit. When first attacked, they flower almost normally, but the fruit is small and dry and shrivels up before ripening, so that little or no fruit is ever produced from an infected bush. Of the three varieties commonly grown, Cuthbert, Marlborough and Herbert, the Herbert seems to be freest from the disease. The other two varieties are quite susceptible, but one rarely sees signs of leaf curl in the Herbrt.

So far as is known the disease is not due to any parasitic organism. It apparently belongs to that type of trouble which has been called physiological disease, and could therefore be put into the same class with peach yellows and little peach, and the mosaic diseases of tomatoes, tobacco, potatoes, and so forth. No records are available as to how the disease is brought into the field in the first place, nor how it is transmitted from one point to another. It undoubtedly does spread once it becomes established in a plantation, and many fine plantations are known to have been greatly injured by the presence of a large number of leaf curl plants. If the disease corresponds closely with the mosaic or yellow disease, one would suspect that it is carried either by insects or pruning operations.

Although too little is known about leaf curl to advise a sure means of control, one should always remove the affected plants as soon as they show signs of disease. They are of no use in any case and are likely to spread the disease to other parts or the plantation. In taking out leaf curl plants, one should be careful to get the whole of the root system, otherwise the parts that are left will start to grow and produce new shoots which will also show leaf curl. It is possible that some of our leaf curl originates from nursery cuttings and some care should be taken when setting out a new plantation, to avoid the disease.

METHODS OF RENEWING A STRAWBERRY PLANTATION

There are several methods of renewing a strawberry bed, and these depend on the way the plants were originally set. Most garden strawberry patches are originally set and trained for the matted row system, but if neglected they become a matted bed. This reduces size, flavor, and quality in th berries, and makes it difficult to pick them. To overcome, or guard against this condition, the plants must be kept thinned out and healthy.

For a small garden patch, thinning is not a difficult task, and consists only in removing the excess plants. This is done by the use of hand tools such as the common wheel hoe or the hand hoe. Some sort of cultivator should

be used first to tear up as many plants as possible, then the remaining ones that are not to be saved are cut out by hand. The plants to be saved are left in a narrow row where the original row was planted. From this row, the weak and old plants are removed and destroyed. thus leaving only the strongest and most vigorous plants properly spaced form the basis of the new bed.

The plants selected to remain should be young ones, and preferably those that have never borne a crop.

The cultivation and fertilization operations are the same as for a new plantation.

TRAINING AND PRUNING GARDEN TOMATO PLANTS

When growing tomatoes in small quantities, better results are obtained if the tomato vine is trained to a stake or to a hoop elevated on three stakes and the vine tied to the hoop. This lifts the vine above the ground and permits a free circulation of the air, according to Dr. E. P. Sandsten, of the State Agricultural College. Dr. Sandsten says:

"By removing a portion of the branches of the plants, greater growth is obtained on the main stem and the tomatoes produced are larger and will mature earlier than if the vine is left to grow normally.

"It should be understood that a plant treated as indicated above does not produec as heavy a crop as one left to grow naturally, but for early fruit, this method should be adopted.

"It is not advisable to prune the tomato vine so as to expose the fruit to the sun. Exposed fruit will color a little earlier than when grown in the shade, but the quality will be considerable poorer and the fruit will ripen permaturely. Much better results are obtained by permitting the foliage to shade the fruit thruout the growing season."

PRUNING GOOSEBERRIES

When pruning gooseberries and currants it is well to remember that the finer and most fruit is born on the younger wood. Two-year-old wood is at its best. Four-year-old wood is not nearly as good. Cut off the oldest canes each year at the surface of the ground and thin out the weakest of the young growth, leaving the stouter shoots for renewal. Eight to twelve canes make a bush of ample proportions.

Growers sometimes clip back the annual growth. The effect of this practice is to increase the denseness of the bushes. This is not desirable, as the bushes are generally sufficiently crowded and difficult to pick. Renewal can be secured most effectively by saving some of the young sprouts which spring up from the roots each year.

SUMMER PRUNING

The question is asked many times each season: "Is the summer pruning of fruit trees practicable and advisable?"

The answer is no, except in a limited way. Small branches and water sprouts may be removed without harm to the trees, but the cutting off of large branches is debilitating. It may be said in favor of summer pruning that wounds made in the growing season heal quickly, and it has been asserted that summer pruning hastens fruit bearing, but this is not fully settled as a matter of fact.

In practice pruning when the leaves are on is very difficult. It cannot be done with a fair degree of spced except in the case of removal of dead branches. When the leaves are in the way one cannot see which branches should be removed without consuming much time; besides, after a branch with leaves on is cut off its removal from the tree is difficult. When the trees are bare and the weathes mild is the only psarticable time to prune fruit trees.—Ohio Ex. Station.

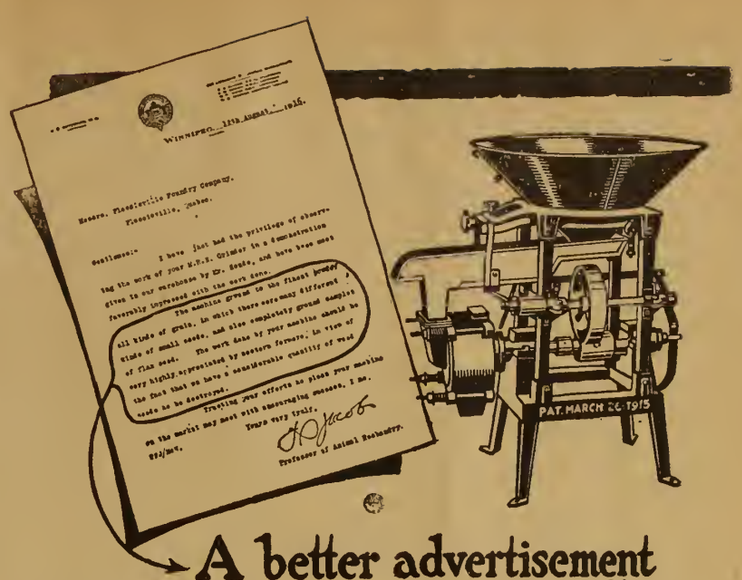
MORE MANURE FOR THE ORCHARD

The crying weakness of most farm apple orchards is lack of fertility. Heavy crops of apples, whether clean or scabby, take a lot out of the soil, and the trees are bound to show poverty in foliage, with consequent lack of fruit if manure is not applied regularly, in sufficient quantity. If we were obliged to grow one crop year after year on the same piece of land, we would never be able to satisfy ourselves with the quantity of manure applied. no matter how great our source of supply happened to be, and we all know that anfthing short of a Herculean effort to keep up fertility would mean a steadily diminishing crop.

The poor old apple orchard is struggling to produce the same crop year in and year out, the averaye attempts at putting back the fertility are far short of an effort that would do credit to Hercules. It pays well to apply manure to the orchards in the winter time. Chemical fertilizers are useful, but in my opinion they cannot take the place of barnyard manure; I like to use both, but the price of the chemicals at present is an important consideration. The only economy that should be used in manuring is to place the material only over the feeding roots of the trees, keeping about five feet away from the trunks in all directions.—Dr. A. J. Grant, Thedford, Ont.

THE BEAUTY OF WEEDS

The destruction of weeds is, of course, one of the great objects of the summer fallow. Doctors tell us that the laws of disease, rightly understood, are not less beautiful than the laws of health, and there is a varied beauty in a crop of deeds that will scarcely be found in a crop of wheat. Some weeds adorn themselves with flowers of flaming yellow, the burr and the cockle put forth gentle little buds of blue, even the stink-weed has a silver tip, and the leaves of the pigweed are glossy and smooth. To the good farmer, however, their beauty appears like that of the spotted snake. hiding venom under its gloss, and when the plowshare has gone through them and the black soil has rolled over them, the field has far more beauty for his eye. This illustrates again the truism that the real beauty of anything consists not so much in color or form, as in its fitness for the purpose for which it is intended. The curve in the moldboard of a plow has a beauty of its own, but the same curve in the landside would be a detestable ugliness, and so it is that, however beautiful a field of flowering weeds might appear to an artist. to a farmer, the sight of their roots turned up to the sun has a far more bewitching loveliness.



Facsimile copy of letter from Professor of Animal Husbandry at Manitoba Agricultural College endorsing the M-re.

A better advertisement than we could write
The MRE GRAIN GRINDER has revolutionised Grain Grinding

It is a well known fact that steel plate grinders do not give the same high class chop as that obtained by the old fashioned stone grinder. But the M-re Grain Grinder will give as good chop as that of the best old style stone grinders for the simple reason that its emery wheels grind the grain to a fine powder while the steel plate grinders only slice the grain. We guarantee this absolutely and are ready to prove it.

Here's the Letter:

Manitoba Agricultural College

Gentlemen:—

I have just had the privilege of observing the work of your M-re Grinder in a demonstration given in our warehouse by Mr. Houde, and have been most favorably impressed with the work done.

The machine ground to the finest powder all kinds of grain, in which there were many different kinds of small seeds, and also completely ground samples of flax seed. The work done by your machine should be very highly appreciated by western farmers, in view of the fact that we have a considerable quantity of weed seeds to be destroyed.

Trusting your efforts to place your machine on the market may meet with encouraging success, I am,

Yours very truly,
H. JACOBS,
Professor Animal Husbandry.

The M-re is more Economical in Every Way

Not only does it give a better chop but its output is equal to that of the best steel plate grinders. Furthermore, the emery wheels will last three or four times as long as steel plates and can be dressed in a few minutes, giving practically a new set of plates. The M-re is the only grinder that will completely destroy all wild seeds.

Money back if not satisfied

We will place the M-re Grain Grinder on trial upon your farm, so that you may put it to as severe and thorough a test as you like and if it does not do all that we claim, you have only to return it at our expense and get your money back.

Made in 5 sizes. Send for free booklet illustrating and describing the wonderiul M-re Grain Grinder and sample of chop. : : : : : : : :

BUMPER GRAIN CROP

Reports to the Maritime Farmer from all sections indicate that the biggest grain crop in the history of the Maritime Provinces is being harvested. From every section comes rosy and encouraging reports. The only set-back has been to the buckwheat crop, which in some sections was affected by the August frost. Otherwise the outlook is bright. New Brunswick expects to harvest at least 800,000 bushels of wheat of an exceptionally high grade. The oat crop is a booster and will help in large measure to solve the feed problem. Prince Edward Island and Nova Scotia are equally well situated. The hay crop, unfortunately, is not what it might be in some sections, the estimate running as low as a sixty per cent crop in places. From other sections, however, the reports are favorable.

DAIRYING.

SOME COMMON DISEASES AMONG COWS AND HOW THEY CAN BE CONTROLLED

A very common disease amongst cows is an abnormal appetite for foreign bodies and indigestible substances. Cows so affected will eat old shoes, rags, wire, manure, stalks and any other indigestible substance that they happen to procure. This affects the family cow much more often than it does cows that are in a herd. It is supposed by most authorities that this condition is due to a slight derangement of the digestife system. Cows will leave good nutritious feed of the very best quality to eat stalks and manure and seem to relish them. This would indicate that the condition is due to an unbalanced ration.

As soon as it is noticed in a cow special attention should be paiad to the ration, says Dr. G. H. Conn. A liberal allowance of salt will sometimes remedy the trouble, but in case it does not, one ounce of tincture of iodine should be placed in an eight ounce bottle and the remainder filled with glycerine. Give the cow one ounce of this mixture night and morning. If this condition is not corrected in some cows they will become unthrifty, hide bound, lose flesh and frequently suffer from a complication of diseases. Cows that are so affected should have the mouth examined for any possible injuries.

Overfeeding

Overfeeding usually affects the family cow, especially the city-owned cow. Most of these cases do not present any predominating symptoms by which the condition may diagnosed. The feed that such cows receive and the manner in which they receive it warrants us in diagnosing all cases that show no pronounced symptoms as this condition until something shows up that enables us to make a correct diagnosis. We are justified in treating all obscure diseases of city cows as overfeeding until recovery takes place or until symptoms show themselves by which the condition may be recognized.

The first and most important thing in the treatment is the taking away of all feed. Allow water often but in small quantities. Give a laxative of epsom salts and enforce starvation until recovery.

Loss of Appetite

The animal usually, if not always, fails to present any symptoms by which the veterinarian can arrive at a solution of the cause of the trouble. The cow just seems unnatural and does not have the appetite that she should have, sometimes failing to eat at all. As nothing else seems wrong the owner often fails to call the veterinarian until two or three days have elapsed. Even after careful examination one wil be unable to find anything that would indicate that the cow is sick . It is due probably to a condition of the nervous system that governs the digestive apparatus, possibly a temporary paralysis. The cow refuses to eat and it may be anywhere from two or three days to a couple of weeks before she resumes eating.

Our treatment for this condition must necessarily be experimental since we do not know the exact cause o fthe condition, but our best results have come from the use of the following: One ounce of fluid extract or nux vomica with three ounces of dilute hydrochloric acid, one tablespoonful of this mixture to be given in a half-pint of water three times each day.

Dyspepsia

Dyspepsia is also known as indigestion or gastro-intestinal catarrh. It may be the result of a varied and widely different set of conditions—irritant or spoiled foods; foods that are binding in nature, thus hindering the secretion of digestive fluids and preventing the absorption of the nutritive elements of the food that is eaten; feed that is too fibrous and that may contain too much indigestible matter, or feed that is used over too long a period of time and in too large quantities. Lack of exercise will also predispose to this condition.

The animal has an irregular appetite, is listless and the eyes seem sunken. Constipation and diarrhoea alternate and the manure that is passed is usually dark and foul-smelling and in small quantities only. Occasionally the animal may be heard to grunt and chews the cud only at intervals. The passage of manure almost ceases, but small quantities of mucus are passed. The ears and the base of the horns are alternately hot and cold and the animal lies down most of the time. She may carry a slight temperature. The animal gradually gets weaker and loses flesh rapidly; finally the milk flow has entirely ceased and the cow reels and staggers when she attempts to walk. In many cases a brain disturbance is noticed at about this time, due no doubt to the pain and general weakness and to the poisonous products that are absorbed from the digestive tract.

The very best and most appetizing feed should be offered several times each day and if the animal eats at all care should be taken that the digestive organs are not overworked; water should be given and should have the chill removed. Treatment of this condition is of grave importance and should be prescribed by a veterinarian after he has examined the case. Possibly the treatment prescribed for loss of appetite would give as good results in the majority of these cases as anything that we might be able to suggest or advise.

Colic

This condition is most often produced by drinking freely of cold water, and as the animal usually suffers a chill shortly after drinking and immediately before the colic starts, the cause of this condition cannot be doubted.

The animal begins by kicking at the abdomen with the hind feet and stepping from side to side in the stall. The pain becomes very severe and the animal will throw itself to the floor. In some cases bloating is present.

In mild cases walking exercise for ten minutes or so will sometimes relieve the condition. A tablespoonful of tincture of capsicum woll usually be all that is required. It should be given with milk or water as a drench. If a vetreinarian can be had and no bloat is present, a hypodermic injection of morphine or some other hynotic is al that is required.

Dysentery

Dysentery is, simply speaking, a severe diarrhoea, which may be caused by the eating of irritating or spoiled feed, exposure to inclement weather, parasites, indigestion and the like.

At first the stools are soft, but gradually get watery, often foul-smelling, and are sometimes streaked with blood. The animal has an anxious expression, is haggard in appearance, is weak, and may show some evidence of abdomina lpain. The appetite is lost or is irregular and the animal rapidly weakens and loses flesh. If the condition is not remedied early it may result in death.

If the cause is due to the feed or to parasites, cure can be made either by changing the feed or by the administration of suitable vermifuges to cause destruction of the parasites. A dose of castor or linseed oil should be given and should be fololwed by two or three tablespoonfuls of the following mixture: Tannic acid one ounce, pulverized sulphate of iron two ounces and sodium salicylate two ounces, all thoroughly mixed. This should be given in a solution of water, about one pint being sufficient.—Dr. G. H. Conn.

THE VALUE OF SEPARATOR SKIM MILK AS A FEED FOR PIGS

The Department at Ottawa recently issued a circular calling attention to the value of skim milk as a pig feed.

The following from W. E. Graves of The De Laval Separator Company is interesting in connection with this circular and the effort being made for "More pork."

We know today that nothing will make the progessive farmer so independent, or give him such a steady and unfailing income, as keeping properly feeding and caring for a good herd of cows, raising the choice calves and feeding the remainedr of the skim

Kerosene, the Cheap Fuel

Here's the Genuine Kerosene Engine that Gets More Power

IT has been calculated that with an engine you can grind your grain for less than 2 cents per cwt., fill your silo for about $2.50, separate and churn from 12 cows for 1¼ cents per day, and pump your water for about a cent a day. Unlike other kinds of power, the Engine stops being an expense the moment you finish the job. These figures are based on gasoline as fuel. *Kerosene is even cheaper*—if used in a *real* Kerosene burning engine. The

Renfrew Kerosene Engine

is a *true* coal oil burning engine, designed for coal oil, not adapted. Built on principles applying particularly to *kerosene*, it gets the last ounce of power out of every gallon with minimum carbon trouble.

No adapted engine can get the vaporized kerosene into the combustion chamber warm enough because such engines are built on gasoline principles. But the Renfrew is a *real* Kerosene burner; it gets the vaporized fuel to the right place *quick and hot*. Thus it gets the full power from both the compression and explosion of the vapor.

The Real kerosene engine demands a fat spark, must have it. The Webster oscillating magneto and igniter is designed especially for Kerosene. It provides the proper spark. The special kerosene mixer equipped with auxiliary air valve, ensures properly mixed charge for either full or light loads. In short, the Renfrew is built for 100 per cent. Kerosene efficiency—and *gets it*.

The Renfrew is available in sizes from 3 to 14 h.p. on skids, or mounted on wheels. Our calague describes these and many other interesting features Write for it today.

Renfrew Jr.
Gasoline Engine
1½ h.p.

No need for special shafting for reducing speed; special secondary pulley reduces speed for pump, grindstone or cream separator. Write for catalogue.

THE CANADIAN SALT CO. LIMITED

milk, together with about all the other by-products raised on the farm, to a bunch of pigs.

We have been told of the profit from the good old cow, the foundation of thi sbusiness—how she restores fertility to the soil and how well it pays to raise her offspring. But of the "pig end" we have heard but ltle, and that is the end I am going to say a few words about. Here in the Middle West the pig is a very important part of the farming business. Many a cream separator has been sold because the wise buyer wanted the warm, fresh skim-milk to make his little pigs grow and thrive.

Today we are facing this proposition: In every place where milk is produced in quantities, condensaries are springing up like mushrooms owing to the very high prices of condensed milk. While this condition may be only temporary, these condensaries are paying very high prices for milk and are telling the cow owner that the skim milk is of but little value to him on the farm. If we expect to sell cream separators we must do something to offset this argument, and right here is where the pig comes in.

The market price of heavy hogs is $18 to $20 per 100 pounds, live weight, and corn is $2 a bushel. One of our experiment stations, a short time ago, took 16 pigs from two litters and divided them into two pens, 8 pigs in each, as nearly equal as to size and quality as possible, and started to feed them. Ten pigs in one pen were fed in the proportion of 3 bushels of corn, with water and slop, but no skim-milk and the others were given a ration in the proportion of 2 bushels of corn and 100 pounds of fresh, warm skim-milk from the cream separator. When they had rearhed the weight of about 125 pounds the pigs which had 2 bushels of corn and skim milk were more thrifty, looked better and weighed on an average of 12 pounds more than the pigs that had been fed 3 bushels of corn and no skim milk. In other words, 100 pounds of skim-milk had produced better results than one bushel of corn and was therefore worth as feed more than $2 the price of the corn.

One reason why the skim-milk is better as a feed for young pigs is that it more nearly approaches their natural food. When he young pig is weaned and given strong, coarse grain, his digestive system has not become strong enough to absorb it properly and he becomes stunted in growth for a time—sometimes permanently so. But if he can have plenty of good, warm separator skim-milk, with all its natural body-building properties, he will grow right along and make a good thrifty hog. No farm animal ever appreciates his food or shows more growth in return for proper food than the pig.

How to Feed Little Pigs

Every farmer who keeps cows should have from two to ten brood sows, the number depending upon the quantity of skim-milk he has to feed. These sows should be bred to a good sire so that they will farrow at suitable times in the spring and fall. These mother pigs should not be fed heavy, heating or fattening foods previous to farrowing. Give them a warm slop of skim-milk and bran or middlings, with some green food if possible. At the time of farrowing they should be watched closely for a few days so that they do not injure the young pigs. This, furthermore, will give you a chance to become acquainted with them.

The average litter will be from 7 to 15 and all can be saved with care. When the little pigs are about 3 weeks old make a hole in the pen where they can get out and away from their mother. Then put agout two quarts of separator milk in a shallow dish where they can get to it, and see what will happen. They will take one sniff of it and if they can they will all be in the pan the next minute. In 3 weeks they will be waiting for you and the skim-milk. No need to put up a sign "Watch Us Grow," for you can see it every day. If you follow this course you have taught them to eat before they are weaned and by feeding them the same kind of food, they grow right along and are never stunted.

THE CALIFORNIA DAIRY COW COMPETITION

Another great breed victory has been won by the pure bred Holstein-Friesian and her grade sister in the California State Dairy Cow Competition. This competition has been running eighteen months but only ten months production was taken so that this gave the competing animals time to freshen again somewhere near the end of the year, and yet make a large record.

Two hundred and forty-three animals completed the ten months test. Of the lfteen cows producing more than seven hundred pounds of butterfat in the ten months no less than thirteen were Holsteins. First, second, third and fourth places are held by registered Holstein-Friesians, a Guernsey comes fifth; sixth and seventh places are taken by Holsteins while a Holstein grade comes eighth and the best our Jersey friends could do is tenth, as the report shows, she made a very creditable showing both for milk and butterfat.

They certainly grow some great cows in California and all great California cows are not black and white, but this competition again shows what has been demonstrated many times before, and that is, given an equal chance, the Holstein cow stands supreme as a producer of butterfat, and as a producer of milk, she stands alone.

Some of the honors may be summarized as follows:

1. The cow which made the most butterfat in ten months was a Holstein.
2. The cow which made the most milk in ten months was a Holstein.
3. The cows which won the two University of California gold medals for butterfat production were Holsteins.
4. The grade cow which made the most butterfat in 10 months was a Holstein as was also the second highest grade.
5. The grade herd from 10 to 25 cows which made the highest average for butterfat for ten months was a Holstein herd.
6. The grade herd of more than 25 cows which made the highest average for butterfat for ten months was a Holstein herd.
7. The herd of five cows (registered) which made the highest butterfat average for ten months was a Holstein herd.
8. The herd of five cows (grade) which made the highest butterfat average for ten months was a Holstein herd.
9. Nearly half of the monthly prizes for average butterfat production of herds were won by Holsteins.—Holstein-Friesian Association.

MORE FLY CHASERS FOR THE DAIRY

The best method of combating flies is to prevent their breeding. Two kinds of flies are especially annoving to the dairyman. The first, the house fly breeds in filth and feeds on spilled milk and the like. They do not cause cattle serious discomfrot, but are a continual source of danger to the milk supply. Therefore the man who is desirous of supplying his customers with the best grade of milk should do all in his power to get rid of them.

Careful screening of the barn and manure pit will help, and if the manure pile is occasionally sprayed with a solution of borax, one pound to twelve gallons of water, a decided reduction will be noted. A poison bait composed of one pint forty per cent. formalin, eight pints fresh milk, and eight pints water sprinkled round the stable two or three times daily, will be found satisfactory. Arsenicla poisons are always dangerous when used near a dairy. There are also endless types of traps, most of which are of value if baited with banana peel or a fish head.

The second class of flies is the small black kind. These cause cattle more or less discomfort, and though recent trials show that the effect upon the milk flow has been exaggerated, nevertheless their presence greatly annoys milkers and many sprays have been devised to repel them. The following mixture is valuable and easily prepared: Two gallons creolin, one gallon cottonseed oil, and ten gallons water. Mix thoroughl and apply with a hand sprayer.

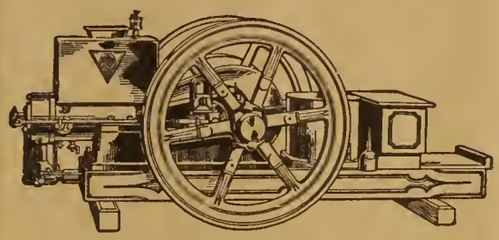
Fish oil, tar and the coal-tar derivatives form the basis of most of the sprays. Three parts of fish oil and one part of kerosene, shaken together and applied with a sprayer, is very good. Two pounds of rancid lard, mixed with one pint of kerosene until a creamy mass forms and applied with a cloth or the hand, also gives good results.

One part of crude carbolic acid to ten parts fish oil is also good, but should be applied lightly and without rubbing, as there is danger of blistering if used in quantity. Still another is 100 parts fish oil, 50 parts oil of tar, and 1 part crude carbolic acid. This is a good reliable spray and can be applied with a spray pump without danger. It will often keep the flies away for two days. All sprays have an injurious effect on the coat of the animal and should not be applied to those animals that are tto be used for show purposes. The effcet is not permanent but rather produces a dirty looking skin which is difficult to clean.

When cattle are on pasture and cannot be visited daily, the following spray is excellent, as it lasts several days: Two parts fish oil and one part pine tar. Apply with a paint brush to parts most affected.

"MACHINES MUST TAKE THE PLACE OF MEN"

Let the "Alpha" do your work



Grind Feed
Saw Wood
Pump Water
Run Separator
Churn or Washing Machine

AN ALPHA Engine is almost indispensable on the farm these days when labor is so hard to get. It's so reliable, too. Always on the job. Never quits. Never gets laid up. You can always depend on an "Alpha."

Thousands of Canadian engine-owners swear by the ALPHA because they have found that it is reliable at all times and under all conditions. It is sturdily built. It is simple in construction. It is powerful. It runs on either gasoline or kerosene and develops its full published horse power on a minimum amount of either. If you want an engine that you will be thoroughly satisfied with, put your money into an ALPHA.

Ask for catalogue, prices and complete information. Made in twelve sizes, 1 1-2 to 28 H. P. Each furnished in stationary, semi-portable or portable style, and with hopper or tank cooled cylinder.

FORTIERVILLE, QUE.

WHAT IS THE PURE BRED SIRE WORTH?

(By Prof. W. H. Tisdale, University of Saskatchewan, Saskatoon.)

Prices, considered by some as more than fabulous, have been paid during recent years for pure-bred sires, and it would seem that a panic or craze of this kind strikes the livestock world almost periodically. Is it a panic though, and are such prices unjustifiable Results obtained in various cases and under varying conditions would varify the statement that "it is rather difficult to really estimate the true value of a pure-bred sire in the herd or flock."

Whitehall Sultan, one of the greatest Shorthorn bulls in American Shorthorn history sold as a three-year-old for $2,500. Was he worth it? The answer is very definitely given in the estimation that 60 per cent. of all the Ssorthorn winners at the International for a period of fiv eyears were strong in his blood. He was the sire, in his time, of 82 bulls and 51 heifers. Eighty of these bulls sold at an average of $915, or a total of $73.200. Thirty-six of the heifers sold at an average of $661, a total of $23,800, thus making a totaal of $97,000 for the get of this wonderful bull. Was he worth $2.500 as a three-year-old? Yes, and twenty times that amount. Any good bull in a pure-bred herd is worth that money if he has ample oportunity to make his influence felt.

The majority, however, are more interested in th eproduction of livestock for commercial purposes rather than for breeding and for them the question as to the sire's value must be answered in another way. An answer can be found in the increased value at marketable age of the offspring from the pure-bred sire mated with a bunch of common females as compared with the offspring from a common nondescript bull mated with a similar group of females.

A photo accompanying this article shows sire, dam and offspring. Glenmere Proud Lad, standing at the left, is a pure-bred Aberdeen-Angus bull, proud as his name would indicate, masculine, well made, weighing over a ton and covered with a wealth of thick natural fleshing. His breeding lines run pure for generations back and he has the necessary conformation to back them up. The cow standing in the centre, is a common, red, grade Shorthorn of no particular bredeing, rather upstanding, somewhat angular and lacking greatly the make-up of a typical beef animal. In the third animal of this family group, we have the result of mating these two—a polled steer, black in color, low set, blocky and in every respett a creditable butcher's model. At 23 months, he weighed 1,350 pounds, and at 36 months tipped the scales at 1.670 a weight attained in the usual way; running with the dam for seven months and after that fed upon the grains and roughage ordinarily raised on any farm throughout the country. In order to realize the greatest profit, this steer should have been sold, not later than 2½ years of age, but being valuable for demonstration purposes, he was kept until years old, at which age his 1.670 pounds brought 15 cents per pound upon the Winnipeg market, a tota lprice of $250.50.

On the other hand, let us supose that this common grade cow had been bred to a mean, common, scrub bull, weighing 1.300 pounds at maturity, and devoid of any creditable conformation or breeding. What weight could we expect a male calf of such breeding to attain when three years old? At the most, it would keep it hustling to run much over the weight of its sire, 1,300 pounds. This means a difference of 370 pounds in favor of the well-bred steerfi or, in other words, at 15 cents per pound a difference in value of $55.50 between the two. A carload of the 1.670-ponders would help materially in paying the long price for the pure-bred sire.

In the second photo, a very interesting family group is portrayed. The ewe at the left hand side of the group is the mother of the five sheep, they being the offspring of three successive years. She is only a common grade, seven years old at the present time, and cost the University $4.80 along with 100 females of similar breeding and similar price in 1913. Being herself of no particular breeding, the influence of the pure-bred sire, to which she was mated each season, is quite marked in the case of the lambs. They all conform to the particular sire's conformation and breed characteristics. The two wethers at the extreme right are 1916 lambs, two years old at the present time, and have just recently passed over the scales at a combined weight of 400 pounds. They sheared ten pounds of wool each in the spring of 1917, and are carrying at least 12 pounds each this season. The sire was a pure-bred Shropshire of good size and breeding and the medium-sized body and typical Shropshire covering of wool about the head and legs is readily noticed in the case of the grade wethers. In the centre of the group is noted a pair of broad, low down, thick set shearling wethers, the 1917 lambs, sowing every evidence in their makeup and facial characteristics of having been sired by a Southdown ram. Their combined live weights go to make up 250 pounds of real choice lamb, anad they are carrying about 17 pounds of wool between them. This year the old ewe broke away from her record by giving birth to a single lamb only, sired by a pure-bred Hampshire ram. As an individual, however, it bids fair to surpass any one of the other four, weighing 60 pounds at 9 weeks of age. Here, again we find the breed characterictics of the sire showing up very plainly. Besides raising these five lambs in three years, the old ewe has yielded three fleeces weighing a total of 21 pounds during the same period.

Two lessons may be gleaned from this second photo. The first is this, no matter what the breed of the sire used, equally good results were obtained in so far as the particular breed is suited to a certain market requirement. The pure breeding on the part of the sire leads to a satisfactory, uniform result, and it is easily demonstrated that he is a wonderful factor for improvement in the flock.

Secondly, the old ewe has proven clearly that she and others of her kind constitute the best investment that the farmers of this country will ever have the oportunity of making within the next ten or fifteen years. Note in the following summary, the financial returns in this particular case.

Wool

1916	Ewe 7 lbs. at 32c. per lb...	$2.24
1917	Ewe 7 lbs. at 61c. per lb...	4.27
	Two wethers, 20 lbs., at 60c	12.20
1918	Ewe 7 lbs. at 60c. per lb...	4.20
	Two wethers, 24 lbs., at 60s	14.40
	Two wether lambs, 17 lbs., at 60r.	10.20
		$47.51

Mutton and Lamb

2	Two-shear wethers, 400 lbs. Mutton at 15c.....	$60.00
2	one-shear wethers, 250 lbs. mutton, at 16c.	40.00
1	1918 lamb, 60 lbs., lamb at 18c	10.80
		$110.80

The wool easily offsets all cost in connection with the feeding and management of these five sheep from the time the ewe first lambe din the spring of 1916, thus leaving the lamb and mutton as clear profit. This total of $110.80 is not bad profit on an initial investment of $4.80, anad only goes to show the good returns that may be realized fro ma vigorous, healthy farm flock. Of course, it is not to be expected that every ewe in the flock will yield as good returns as this one has done, but a lambing percentage of 100 is not extraordinary, and it is at the same time very remuneratipe. Wool, too, gives every evidence of remaining high in price for several years to come and there is every reason to believe that a few hundred dollars invested in sheep will yield anywhere from 25 to 50 per cent.

THE FEEDING OF CALVES

Giving a calf an extra good start the first six months of its life, and doing so cheaply, is the secret of successful and economical stock-raising. No matter how good the calf at birth, it will be handled at a loss, or more or less seriously handicapped for future usefulness and profit, if not fed carefully and cheaply in its early days.

HERCULES Leather-Chain Trace

A harness is as strong as the trace—no stronger. The trace takes the strain and the strongest trace is the best. The Hercules is a flat shaped trace, strong as steel, flexible as leather, tough and unbreakable, made of steel chain covered with heavy leather neatly finished in turned and rounded edges strongly stitched. Powerful heel chain and either clip or bolt piece at hame end; one and one-half inch solid leather billot. Does not chafe the horses and is tremendously satisfactory. If you don't have the Hercules Trace on your heavy harness, don't wait order a set NOW. If your dealer does not have it, order from us direct. We will ship same day, on receipt of price.

RD. ED. MORIN & CO., Limited, Quebec, Can

milk practically exclude this product being used to any extent in calf-rearing, although it is absolutely necessary for the first three or four weeks, if best results are to be obtained. To discover the best substitutes for whole milk and the best methods and practices in calf-feeding, a large number of experiments have, during the past three years, been conducted on the Dominion experimental farms. A few deductions from these experiments are given herewith:—

1. It is more profitable to breed and read good young stock to maturity than to purchase the average cows for sale, which are usually the animals least profitable and desirable in the neighbor's herd.

2. The cheapest way of building up a good herd is to raise it. The feed costs of good rearing in Canada range from $16.00 to $24.30 for six-months' calves, $24.00 to $45.00 for 12-months' calves, and $37.00 to 74.30 for 24-months' heifers, the variation depending on methods of feeding, feeds available and market values of these feeds.

3. Calves of poor type and bereding are not worth rearing, but good calves properly bred will be worth at least 30 per cent. and up to 100 per cent. more than their feed cost at two years of age.

4. Calves of good size, strong constitution and large capacity will, on the same feed, make greater growth and better gains than small, weak, narrow individuals.

5. Good rearing of calves is most profitable, as shown in such results as

Earlier maturity in size.
Earlier maturity in profitable production.
Greater production throughout the whole life time.
More valuable and in greater demand at the highest price.
Healthier stock.
More durable animals.
Better able to consume most profitably all cheap farm-grown roughages, and convert these into milk.

6. The calf reared on its dam costs 25 to 50 per cent. more than the pail-fed calf, and the more productive the cow the greater will be the charges against the calf.

7. Pail-fed calves, reared to six or eight months largely on whole milk, make gains which cost $14.40 to $18.75 per cwt., which is several times the cost when a properly-fed substitute for whole milk is used.

8. Skim-milk fed sweet and at a temperature of about 90 degrees fahr. is the best single substitute for whole milk, and may reach a value of 70 cents per cwt. or more in feeding young calves. However, skim-milk may be improved by the addition of a good cream substitute such as flax-seed jelly, oatmeal, or a well-balanced calf meal.

9. Buttermilk, if fed uniformly as to acidity and temperature, may have a slightly greater value than skim-milk. Great caution must, however, be taken to start calves at a greater age and very gradually.

10. In feeding calves to six or eight months of age on rations composed largely of skim-milk or buttermilk and a good cream substitute, gains may be made at a cost of feed amounting to from $2.00 to $7.15 per cwt., this amount varying with the character and price of meal and the ruggedness and thrift of the calves.

11. If well started on mother's milk, calves may be well reared on calf meals without whole or skim-milk. However, greater care and attention must be paid to these calves, and even so, gains cost from $5.00 to $15.41 per cwt., or nearly double the cost where some skim-milk is used.

12. In order to rear the best and cheapest cows, all pail-fed calves should be taught to eat, at an early age, cheap and nutritious farm-grown roughages and grains. The best roughages are grass, fine alfalfa or clover hay, swede turnips, mangels and ensilage. Of the grains, oats and barley are unexcelled.

IMPERIAL SERVICE

If you are in doubt about the proper lubricant, *ask the Imperial Oil man.* He will give you courteous attention and sound advice on your lubrication problems. That is part of Imperial Service.

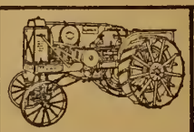
NOT ONLY GOOD OILS — CORRECT LUBRICATION

YOUR automobile, tractor or stationary engine can do its best work only when it is correctly lubricated. Your horses can do their work more easily when your wagons and farm machinery are correctly lubricated. All your machinery will wear longer, give you more satisfactory service and less repair expense if you use the correct lubricant in each case.

There is a just-right oil for every mechanical purpose—an oil manufactured by Imperial Oil Limited for each lubricating requirement. You can get it in any part of Canada—at any Imperial Oil station. There is one near you.

Imperial oils are supplied in steel barrels and half-barrels—convenient, economical. No waste. You use every drop you pay for and know that every drop is uniform and clean.

A Correct Lubricant for every Farm Machine



For Gasoline Engines, Tractor, Auto or Stationary

LIVESTOCK NOTES

H. S. Arkell, Dominion Livestock Commissioner says: "That no doubt sheep prices have reached their maximum, yet I cannot see any reason for any material decline in the price of sheep products for at least ten years.

Tabor C. Everett of Fredericton reports that his sheep averaged him about $6.00 per head for wool this year. Wouldn't have got it if he hadn't marketed co-operatively. Took a lot of coaxing to get him to do it too—won't take any next year.

One of the signs of the times is the number of New Brunswick men embarking in the pure-bred sheep business. The latest are: Dr. John Wier of Doaktown—he is securing stock from Jas. I. Stewart, Amherst Point, Nova Scotia—none better either; The Deilbac Sheep Products Company are putting in ten pure bred ewes, fancy stuff from up country; The Allison people at Rothesay will add a few to their flocks; S. B. Hathaway of Fredericton is asking for quotations on Oxfords; L. C. Box of the Experimental Farm plans to begin with a foundation of 10 Cheviots.

W. H. Venning, Sussex, has some Leicester ram lambs for sale. Good ones too I believe. He has also placed an order for a Berkshire boar. Probably will supply him from MacDonald College, the home of good stuff.

H. C. Jewett, Fredericton, is exhibiting his horses at the Houlton Fair. The Yanks will have to travel some to pull first money in some of the classes.

We were pleased to see Harding Bros. pull down first and second money in the aged bull class at Sherbrooke —it takes courage to go up country; not much though if you can produce the goods.

Breeders report lots of orders for stud sheep coning in—better order before all the good ones are gone.

Some day we hope to see New Brunswick the sheep centre of Canada—no reason why—a lot of work to do yet though.

From now on the wether lambs will gain like the mischief—unfortunately New Brunswcik farmers will not profit from the source—we haven't any, they are all rams. Wonder how long shiftless methods in flock management will persist.

The Hon. F. B. Carvell, Minister of Public Works, has ordered 24 breeding ewes and a pure-bred Shropshire ram.

Get a few sheep to try them out, if you have any fence suitable to hold them. They will help clean up the farm and feed on otherwise waste forage and make you a handsome profit.

If hogs are troubled with rheumatism in fattening or growing a little, nitrate of potash in their feed three times a day will be beneficial. About 3 grains per cwt. is the correct dose.

THE HORSE

TO PREVENT OVERHEATING, SUNSTROKE AND HOME SICKNESS AMONG HORSES

Let your sympathy for the horse find vent in considerate actions towards his comfort when the hot spell is on. August and September are the really trying months on horses, and the two months when horses of all ages and kinds need most attention. They get the week ends to rest, from Saturday till Monday morning, and a few odd idle days or a little occasional slack for a while and these are valuable opportunities wherein to brace up the horse for the strenuous rush of summer and fall work. Few farmers take any advantage of these off times to keep the horse in fit form or spirit for his duties. Too often this off time finds the horses turned loose on some old hoof trodden pasture to hug a fence corner or some poor shade tree and fight flies, that perhaps persistently bunch around an open sore on the shoulder. In all idle periods, during the heat, they should be turned out on fresh pastures at night, if possible, and stable them through the heat of the day with their usual attention to feeding and watering. This is the only way to conserve their energy for the coming fall work. Where there are sore shoulders they should get attention towards healing when in the barn all day, and free from the festering influence of the flies.

The Overheated Horse

Horses that are skilfully and watchfully cared for in summer, so as to keep them in best of health and vigor, can endure a degree of exertion in the hottest days that would strike down an ill-nourished, weakened animal. Grass is the natural feed of the horse, but nature meant it only for the idle horse. The domesticated animal has strenuous duties to perform and requires extra aids to keep up his energy. Without that energy the horse gets weak and is less able to get rid of surplus heat from exercise.

There are several signs that show up to the observant teamster, indicating when the horse is played out with the heat. There are some willing horses, that have ignorant and inhuman drivers, that work in heat till they fall out, either from exhaustion or sunstroke. These horses can be saved if the teamster is alive to the signs that foretell the coming collapse. These signs are the only methods whereby the dumb animal can inform the teamster of his condition.

When horses are working in hot weather and sweat suddenly stops, it is time to examine them. If the horse's hair is dry when expected to be wet and he is panting rapidly, or if he staggers when walking or braces the legs when standing, with general appearance of depression he has been pushed ahead too long. Before the animal gets worse off than that it is best to get him into the shade. A good home stimulant for such cases is two ounces of aromatic spirits of ammonia, or two ounces of sweet spirits of nitre in a pint of water. A pint of warm coffee is also recommended, but be sure it is not too hot, as horses are sensitive to heated foods.

The horses that are most liable to play out in heat are those that are overfat and have not had sufficient exercise, previous to steady work in hot weather, young and immature horses, feeble and ill-nourished and old horses. All these have to be carefully watched in heat while working. In an attack of sunstroke which overfat and also ill-nourished horses are liable to, it will be readily known by the horse suddenly stopping in his work, propping himself up on extended legs and panting violently. The cure adopted in the East by the Arabs, who understand the horse perhaps better than any race, when sunstroke signs appear, is to inject 30 to 60 grains of quinine underneath the skin by hypodermic syringe. No other plan equals this in efficacy.

A horse that has had a breakdown from overheating is never the same horse again, so that careful attention to the health of horses in hot weather, and watching for the first danger signals in the field is most essential. The greatest hustlers with farm operations, and those who get a surprising amount of work done by each horse without ever killing one by heat, are the men that are on the outlook for heat troubles and prepare and feed the horse to withstand them. An overheated horse is a poor piece of property, and the overheating can be avoided.

It is all a matter of sympathy with the horse on the part of the teamster. The horse has the same coat and covering to spend the heat hours of day as well as the colder hours of night. He cannot lay aside his coat on the hot working days and put it on when the colder spells come as does the human co-worker in the field. The harness of the day time also adds to the horse's discomfort from heating. Rigid attention to grooming the horse in the summer time alleviates the sweating and overehating, and the horse must be cooled down before being sent to grass and well groomed before starting the day's work.

The Homesick Horse

It is not generally suspected that kindness and sympathy with the horse in matters of detail that are considered of little value are stimulants towards a lively spirit and better health. They respond to different treatment in a manner that is not generally recognized.

The war has conscripted many of these faithful animals from the farm fields to the war fields of France and Mesopotamia, and the change has manifested this characteristic in the horse in a very visible manner. The recruited farm horse has to go through the same strenuous training as that of the fighting man, and this work has bred home sickness in the horse.

When a horse is homesick all the veterinarians in the world can do little for him. This ailment affects the horse equally as seriously as it does the man at the camp who is carrying a gun. Of all the classes of ailments met with among the horses at camp, that of home-sickness is the most difficult to handle. The men in charge of the horses, those who feed and look after them in the yards and barns, early detect symptoms of home-sickness. When they find a horse standing around by himself, moping and pining, with a vacant stare in his eye, and head hanging dejectedly, they take him at once to the observation ward and a "vet" is called who proceeds to give the animal a close physical examination, but he finds nothing wrong in the way of temperature, respiration or heart beat. In short, there is nothing in the world the matter with the horse that the "vet" can detect. But the soldier who brought the horse to the ward, as well as the "vet" is quick to decide as to what ails the horse.

The horse brought to the observation ward and found to be suffering from home-sickness improves slightly with careful attention and much petting by those in charge. It has been found that human sympathy goes much farther with horses so ailing than any other method that may be followed. It is turned back in the lot with tis former companions with the hope that it picks out a mate. Once a horse has mated up with another horse there is no danger of home- sickness. e eats and drinks regularly, and improves continually. In the event that the horse from the observation ward finds a mate among either his former companions, or some new arrivals, he at once begins to improve in physical condition, and within two weeks is ready for work in whatever capacity his size or individuality fits him. It is usually the horse that is purchased of an owner that gave splendid attention to his horse stock that is afflicted with the trouble mentioned. Where two or more horses from the same farm come to the camp, they are never troubled with home-sickness, as they chum contentedly together and thrive under hard work. It is usually the horse taken alone from a home that was peculiarly attractive to him that becomes homesick, and the greater pet he was at home the more severe his illness will be, unless he takes up with one of the men at the hospital and allows that individual to "baby him."

When nothing seems to relieve the condition of the home-sick horse, the animal grows progressively worse, and in due course of time is stricken with pneumonia.

The lesson is obvious. It is certain that if the conditions and surroundings of the horse are fitted to give him the greatest possible comfort while at strenuous work, he will respond with increased service.

HOW TO SHOE SHOW HORSES

The Results of 30 Years' Experience

Horseshoers and showmen disagree many times on the kind of shoes to use to show a big horse to the best advantage. My 30 years' experience as a fitter and shoer of all breeds of draft horses, besides several years spent in Scotland in the same work, have thoroughly convinced me that more horses have their action ruined by heavy shoes than are ever helped by them. One should vary the weight of the shoe with the size of the horse. A two-pound shoe is heavy enough for a yearling stallion, whereas I sometimes use as much as three pounds in a shoe for an aged horse. If a horse is a bad goer, a heavy shoe will freyuently make him worse. More can be done to perfect a horse's action by correcting as nearly as possible the shape and se of his feet than by loading him with heavy shoes. I always use medium weight shoes, particularly on young horses. One is much surer of getting true action with light shoes on a well-formed foot than he is to try to balance up an ill-saped foot by weight in the shoe. In most cases the well-shaped fot can be grown in time, and ordinarily a horse will go pretty nearly right if his feet have been properly taken care of since a foal. It is useless to expect that a horseshoer can put weight into a shoe so that it

PEERLESS PERFECTION
The Fence For Real Protection
gives life time service. Is made of the best Open Hearth steel fence wire, all impurities burned out, all the strength and toughness left in. Makes the fence elastic and springy. Will not snap or break under sudden shocks or quick atmospheric changes. Galvanized to prevent rust and the coating will not flake, peel or chip off. Can be erected over the most hilly and uneven ground, without buckling, snapping or kinking. Every joint is locked together with the well-known "Peerless Lock." The heavy stay wires we use prevent sagging and require only about half as many posts as other fences. Send for catalog. It also describes our farm gates, poultry fencing and ornamental fencing. Agents nearly everywhere. Agents wanted in unassigned territory.

Absorbine and Absorbine Jr. are made in Canada.

Invaluable on the Farm—

Everjet
Elastic Paint

A lustrous, black carbon paint that combines the qualities of cheapness and durability. Without an equal for use on metal, wood, rubber roofings and all exposed surfaces. It is a bituminous product and is elastic, adhesive; will not rub, peel or scale; will not become brittle and crack; is impervious to moisture; can be used in any climate; resists all action of acids, alkalies, gases, steam vapors, etc. All metal surfaces should be protected against rust with Everjet. Get a can to-day.

Ad. No. 2

will serve the place of the properly turned foot. If the hoof isn't there on which to nail the shoe, it is impossible to balance the foot perfectly, because the weight will not come in the right place. That is why one sees so little uniformity in action as he looks at a string of draft horses at a show. Each horse has been equipped with a pair of shoes which it was thought would perfect his action. Nobody ever saw a good-going horsebare footed that didn't have the right kind of action when shod unless it wasn't done properly.

Differences in Front and Hind Feet

Shoes in front should be perfectly round, whereas those behind should be slightly oval shaped. There should be no toes either on the front shoes or the hind ones. The heels should be blunt and hammered down so that they are very low. A heel on a shoe has no particular value to a show horse except it may save him from slipping. The outer edge of the shoe should be made to fit the foot neatly, with the heel extending only a very little beyond the back edge on the front foot. The hind feet will stand more of a heel to the shoe than the front ones. In fact, I usually make the outside heel o nthe shoe for the hind feet quite a little longer than on the inside. That shaped shoe in the heel will help to throw a horse's hocks together. A similar shoe at the heel in frnot will, of course, help a horse t otoe out. It is particularly advantageous to shoe a horse so that his hocks will stay together a bit. It gives him a better stifle movement and makes him stouter to keep his heels together military fashion. Try yourself and see whether you can lift a heavier load with your feet standing apart or when your heels are close together and your toes out a bit. The same rule applies to the pulling power of a draft horse. The shoes should always be creased in the line of the nail holes, as that helps a horse to grip the ground. The toe clip should not be over an inch wide ond an inch and a quarter high. It should be hammered out very thin, so that if a horse pulls a shoe and steps on it the clip will bend over and not run into the foot. I have seen some bad cases develop from a horse stepping on a shoe with a big stiff clip on it. Furthermore, a wide clip doesn't look well, as it gives the appearance of too much metal on the feet. If I want to do a fancy job, I weld this clip on, but more frequently I turn it up from the shoe.

Important Feature Some Forget

A very important feature about a shoe which many blacksmiths forget is to have the inside edge next to the foot lower than the outside. Most shoes one sees are made higher on the inside than on the outside. The reason for having the ouside of the shoe higher is that the wieght of the animal should come to the wall and not on the sole of the foot. If the sole must bear the jars, the horse will soon go lame, and particularly when he has t ostand on a hard floor or be trotted on hard pavements. Frequently, if there isn't any toe to spare, I take a paring knife and removing just enough of the sole before puttting the shoe on, so that I am sure the shoe will not touch the sole. If a horse goes sor in front after he has been on the fair circuit for a while, it is likely due to his feet drying out, or else to a slight touch of founder from a draft. To pack clay in the bootom of the feet will help, but the best remedy I ever found was to stand the horse in a tub of hot water. Heat will take down inflammation and there is no other way of keeping the water so uniformly hot. To stand a horse in a tub of hot water several hours per day will usually remove the soreness in a short time. If the foot is contracting and causing inflammation inside the hoof walls, the hot water will soak up the hoofs faster than anything else. There should only be four nails on a aside, and they should be driven high up. The last nail toward the rear side of the foot should not be driven farther back than the quarter which is about the middle of the side from front to back. Both the hoes and the crease in the shoe should be set at an angle so that the nail can be driven parallel with the sloop of the hoof wall. Then, by punching the holes slightly to the inside of the centre of the shoe, the nails can be driven high up on the hoof with no danger of pricking. They hold better if nailed on this way. If set near the outer edge and at right angles to the shoe, it is impossible to drive nails high enough to hold well. If a shoe is nailed tightly in the heel, it will likely cause lameness. The reason is evident, for anyone knows that if a shoe is nailed on when the foot is dry and a horse goes out into the mud and soaks up his feet, the shoes are bound to draw very tightly because the foot has expanded with the moisture. Pressure for any length of time will cause inflammation of the sensitive tissues inside the foot wall.

How to Correct Faults in Gait

To shoe a draft horse to improve his gait requires a good deal of skill. One can shift the weight in a light horse and in that way alter his method of going considerably. No one cares whether a race horse goes square or not, if he has the speed. On the other hand, we require that a draft horse move true. The front foot should be picked up and set down straight ahead without any side motion one way or the other. Besides, the hind feet must be brought forward and set down in the same track made by the front ones. The appearance of the set of a foot can be changed wonderfully by shifting the clip a little one side or the other. That does not, however, improve the action at the trot. A paddler can only be helped by shortening the toe on the outside and growing it slightly longer on the inside. The shoe should not be nailed on exactly with the set of the foot, but should be shifted slightly with the toe a bit toward the inside. An attempt should be made to grow the foot so that it stands directly in line with the body, so that when the horse picks up his foot he will carry it forward in as nearly a straight line as possible.—By G. MacLeod, Illinois, in The Percheron Review.

HOW TO BREAK REARING HORSE

I have had considerable trouble with rearing horses and have found that they can usually be broken by the following method and especially if they are young and taken in time: Place a rope or strap surcingle around the body just back of the forelegs and fasten a pulley on either side of this. Take about 20 or 25 feet of ½-inch rope and run the ends through the pulleys. Fasten them around the front legs just below the pastern joints. Keep the loop end in your hand and when the horse is well up in the air, draw his feet up against his belly. When he comes down he will be forced to light on his knees. This is not advisable on a hard road as there is danger of injuring his legs, but a few lessons of this sort on the grass or in a plowed field will not soon be forgotten.

In feeding the colt bear in mind that it is bone and muscle that it needs, and the nitrogenous foods are what should be fed, such as oats and bran.

An ill-fitting collar is liken an ill-fitting shoe on the human foot. You wouldn't wear a shoe, would you, that caused corns, bunions and blisters? Be careful and humane.

Gombault's Caustic Balsam

The Worlds Greatest and Surest Veterinary Remedy

HAS IMITATORS BUT NO COMPETITORS!

SAFE, SPEEDY AND POSITIVE.

Supersedes All Cautery or Firing. Invaluable as a CURE for
FOUNDER,
WIND PUFFS,
THRUSH,

POULTRY.

WHY HENS START EATING THEIR EGGS

Egg-eating hens invariably are found in flocks under confinement, or in small pens. Hens given wide range seldom eat eggs for they are much too busy to contract the habit. Only while laying are they found about the nesting places. During the balance of the day they may be located here and there over the range given them, busily searching for food.

So when turning our attention to curbing this pernicious habit we must consider it from a standpoint of what the hen would do were she given freedom, for we must deal with the hen in confinement. Hens under confinement are those generally contracting vices, among these being egg-eating and feather-pulling. We keep our hens busy by throwing their grain in a deep litter of straw when they are in confinement. This keeps them busy. We like cracked corn, really better than whole corn, for it keeps them busy still longer. Cracked corn is not a better food than whole corn, but the point we wish to emphasize is that of keeping the hen busy. She works harder to satisfy her hunger. We have fed wet mashes, in the belief that it will satisfy their hunger more quickly, and we find it does, but then we have idle hens—the hens that begin to break and eat eggs. I have detected idle hens fighting others on the nests. These hens were not hungry.

Since we have fed protein, as the nature of hens calls for, we have had feed protein in the form of bran, beef scraps, tankage and buttermilk—not all at once, but use that most plentiful or most easily obtained. Here is where many people fail, even when hens have some range. If hens receive no proper amount of protein in their ration they will get a craving for animal food. If they do not get it any other way, they can get it by eating eggs, and they generally get it, too.

I wonder how many of our better halves are guilty of feeding egg shells without crushing them very fine? I have seen this done, and it is easy to comprehend how chickens may be led to eat eggs after being fed whole egg shells. We find it a good practice to slightly roast egg shells before feeding. They crumble nicely then.

As with many evils present in the various lines of farm life, prevention is easier than a cure, and when the habit once presents itself, it is impossible to completely eradicate it by preventive methods. Curative methods must be resorted to. We find that dark nests help much. If the hens can not see the eggs well it will be next to impossible for them to do much damage. Covered nests help much, as do also low nests. Keep hens from standing up in their nests and much of your trouble is conquered.

In cases of a badly depraved appetite for eggs, it is often necessary to catch and sell a few hens so that others may be kept from developing the habit. We have been compelled to do this and would advise others to do the same. Of course preventive measures should be taken at all times, but in extreme cases we advise eliminating the offenders from the flock.

FENCED RANGES FOR THE POULTRY SAVE TROUBLE

On the farm it is often a problem to give the poultry sufficient range without having them run over the garden and the lawn around the house. At certain seasons they can have the run of the farm but at other times it is more satisfactory to have them under control. Fence costs money, but there will be more pleasure in producing poultry and eggs on the farm if certain areas are fenced off for the birds.

The enclosed area should be large enough to insure a supply of green feed throughout the growing season. If the green feed is just long enough to keep the hens picking at the tender shoots without being so long that it will become tough, it is just about right. Poultry enjoy ranging on a nice clover lawn. When the clover and the grasses in the poultry yard are just about like a nice lawn, the yard has a fine appearance and the birds are apt to thrive and be profitable.

The divided poultry range is very practical as this gives the poultryman an opportunity to keep the flock in one side of the yard while the grass is growing in the other. Certain crops can be raised on one side of the range and the birds excluded from that area except at stated times. We have one divided poultry range which can be described about as follows: It is large enough to keep an abundant supply of green feed for about three hundred fowls. Half of it, where the laying house is located consists of an apple orchard. A rich clover sod grows beneath the trees. We know that it pays to plow apple soil but this ground is constantly enriched by the birds and we apply sufficient mulch around the trees so that they do fairly well. This part of the range is abundantly furnished with shade. The other half consists of a clover field and a strawberry patch. The birds have the range of that section except at strawberry time. At other seasons they have not seemed to injure the plants. This combination gives the birds a satisfactory range and they do not attempt to fly over the fence. At present the birds confined on the range are Barred Rocks, and of course they fly less than Leghorns, but if any individuals show a tendency to come over, one wing is clipped and that prevents further escaping.

When a farm flock consisting of old and young birds is allowed to range together, the young are constantly trampled and crowded to one side at feeding time. They develop slowly and in a few years this will result in the entire flock becoming inferior. Of course the young birds are soon old birds and if they do not get a good start while young, the bad influence is soon apparent in all the birds of the flock and the breeding stock will be lacking in vigor and of poor laying ability.

There are two other advantages of the fenced range. The birds are not injured by other stock. If poultry flocks feed around horses, cattle, and hogs, some of them will receive broken legs and wings or other injuries by being kicked and stepped on by the animals. The loss of eggs from stock which has access to the barn and other buildings, is quite large. Some eggs are never found and others are gathered after becoming stale. If the hens are given a clean grassy range and no good place to lay eggs but in the poultry house, they will learn to lay in the proper nests and there will be scarcely any eggs lost. Of course hens on a fenced range can be given the unlimited range of the farm at certain seasons, but the means are at hand to control them quickly whenever it is necessary.

Poultry raising on the farm will bring a larger profit and be considered more seriously when there is more effort made to control the birds. At present they actually are a nuisance on some farms due to the fact that they roost on the farm impements, sun themselves on the verandah, scratch up the garden and keep the entire lawn around the house unfit for human enjoyment. By keeping them under control they are placed upon the same plane as the other live stock on the farm and their management gives much more satisfaction and profit.

R. G. KIRBY.

IN SELECTING BIRDS HOW TO ELIMINATE ALL NON-PRODUCERS

In the poultry yard every farm has its slackers as well as workers. On the average farm from twenty to forty per cent. of the flock should be culled and consigned to the meat market. Due to lack of system and knowledge most farmers have been marketing their best layers and retaining the "big, fine looking hens," along with those that have been "family pets" for the last five years. We need not labor under delusions any longer. There is too sharp a contrast between the high and low producing hen, for us to grope along blindly. Two methods of selection will be dealt with: (1) summer and fall selection; (2) the quality test.

By intelligent culling we mean the elimination of all slacker hens, without any reduction in the egg yield. It also means higher flock averages, lower grain and labor bills, and greater profits.

The comb is the health certificate of the hen. The shriveled, dry, scurvy looking comb of the low producer indicates lack of blood circulation and vitality, while a full bright waxy comb of the heavy producer means vitality and strong blood circulation.

In most cases a late moulting hen is the heaviest layer. She generally defers changing her feathers until the latter part of October or November and quickly moults in again. The opposite is true of the drones, they usually commence in July or August, moult very slolwy, taking from one month to six weeks longer than the producers, then wait until the warm spring weather before trying to perpetuate themselves by laying eggs.

The other method of selection by the "quality test" system can be applied at any season of the year with pronounced accuracy. It is not necessary to winter a large number of hens, to feed and care for them for six months and wait for the signs of production, mentioned in above test, to appear.

A Test for Egg Capacity.

Dealing with the pelvic region, which corresponds to the udder of a dairy cow, we look for the same characteristics in the egg sack of the hen that we do in the udder of a heavy milker, quality and capacity.

Capacity is generally measured by the width or number of fingers that can be placed perpendicular across the abdomen, between the breast and the pelvic bones. This distance varies greatly with different hens. The non-producer has only one or two finger capacity. The slacker, or non-profitable hen, may have from three to six finger capacity, the same as the heavy layer, but it lacks quality, and we measure quality by the flexibility and fineness of the egg sack. A hen with large capacity, but having a thick, fat, flabby egg sack, or an inflated egg sack, will not produce nearly so large a number of eggs that a hen of equal capacity having an egg sack that is thing, mellow and contractable. Therefore, we say the greater the capacity combined with contractability of the egg sack, the more eggs we can expect.

Capacity determines the length of cycle—quality determines the rythm when applied in conjunction with capacity. Both are necessary characteristics of a heavy layer. They indicate the possibilities of the individual mechanism within the hen. The actual efficiency in egg production will then rest with the person operating the machinery.—E. C. FOREMAN.

DISPOSE OF OLD HENS

As soon as the breeding season is over, get rid of all male birds used in the breeding pens. When the egg yield drops in the early summer, or when the egg yield does not pay for the feed, sell off all hens over two years old and even the year-olds cull pretty well. Poultry at this time of the year will bring a better price than later and feed and space will be saved for the best of the year-olds and the growing chicks. Old hens as a rule, especially of the heavier varieties, do not pay for their feed in late summer eggs.

Sell the young cockerels whenever they are ready throughout the summer. Don't keep everything till the fall. Whenever the price is good, sell the cockerels as broilers or as small roasters.

In an experiment carried on at the Experimental Farm in the spring of 1917 with Leghorn chickens, the sale of the cockerels paid all expenses for incubation, brooding and feed for themselves and pullets up until the first of September. When the pullets

went into winter quarters on November 1st, they had cost over and above what had been paid by the sale of the cockerels just 3.9 cents each. This experiment showed not only that it paid to sell the cockerels early, but it also demonstrated that pullets could be raised much cheaper than they could be bought in the fall.

BREAKING UP THE BROODY HEN

There are very few poultry breeders who have not had laughable and provoking experiences with broody hens, for these persistent hens are both amusing and annoying. About the only breeder who does not face the problem of breaking up the broody hen is the man who raises Leghorns, and sometimes these hens become very anxious to be mothers after they have passed two or three summers.

A poultry journal once offered prizes to the readers who would send the best methods of breaking the sitting hen. The editor of that paper must have had some hearty laughs at the plans proposed by his friends and readers, for over 1,500 of them sent in replies, some very amusing indeed. One breeder suggested tying a bright rd ribbon around the hen's neck, with teh bows extending far out at each side. He said the old hen was so busy looking at her tie and admiring herself that she forgot her nest. Another said he placed a roomy coop on a very steep hillside, and the hens could not sit comfortably, so they "took to" the perches he provided and roosted instead of sitting. In a few days they were clear out of the notion. Another said he tied a barrel under a tree, put a wire mesh door on each end of the barrel and put his hens inside. When they tried to cuddle down the barrel kept tilting up and down, as the thing was hung from one rope fastened in the middle of the barrel. Still another advised putting a chunk of ice in the nest, another a piece of slate roofing, and yet another suggested a Teddy Bear. Placing the broody hen in a pen with kittens or pet rabbits will also change her mind, so some one said.

MOULTING HENS

From the number of inquiries which Mr. D. O. Barto has received recently asking for information or directions concerning the proper treatment of hens to induce early and rapid moulting in order to secure an increased number of eggs in late fall and the winter months, it is evident that the idea prevails with many that this method of increasing winter egg production has been proven to be successful.

"However, this is not the fat," says Mr. Barto. "A very careful and thorough experiment to test this question was conducted a few years ago at Cornell University Poultry Experiment Station. The method that is used to produce rapid moulting is to starve the flock for about three weeks by cutting the ration to one-third the usual amount and then rapidly increasing the feed to all the birds can be induced to consume. This causes a rather sudden dropping of the old feathers, but the Cornell Experiment Station found that the hens thus treated produced fewer eggs during the fall and winter and at a greater cost per dozen than did the hens fed normally.

It is better to feed the fowls an abundance of nutritious food, quite rich in protein and fats during the moulting season, but not to attempt to force the moult by any patent stimulating foods.

THE TURKEY MOTHER

There is little use trying to keep turkey chicks on a limited range. They love to walk and also to roost in the open. The turkey hen is an ideal sitter, but a bad mother unless confined, as she drags her young after her, and does not wait for those that fall out by the way so long as one is left.

WASH DAY

Good Soap—
Plenty of hot water—
And a sunny, breezy day !

All are essentials on wash day. But there is a something else thta must not be lacking—a strong back. Advertisers of machinery may write glibly of their labour-less devices, and the editors of home journals may soothingly describe the pleasures of the laundry under modern conditions; but clean, snowy white clothes are always paid for at the price of hard work. In the days when every woman did her own washing, and did it better than it is done to-day by modern laundries, Dr. Chase devoted his talent and experience to keeping women fit for household work. They were the every day physical problems of the Average Man and the Average Woman that interested him. Remember please that is the secret of his success. That is the real reason why his name lives to-day, and will live for the future.

He reasoned in the days of our grandmothers that in order to keep the human machine in good working order, attention must be given to the condition of the filtering and excretory system. And his reasoning rings true in the year of Our Lord 1918. Wherever there is physical work to be done there is need of regulating human machinery by the Dr. Chase Plan of Health.

From his every day experience in the practice of medicine, and as a result of dealing with a wide variety of cases, the doctor realized that the foundation of his Plan of Health must consist of a treatment to regulate the liver, kidneys and bowels.

Everywhere he found people complaining of backache, of rheumatism, of lumbago, of pains in the limbs and of headaches. The woman at the tub as well as the man with the hoe was suffering the results of a poisoned system.

The kidneys failed to filter these poisons from the blood—the liver was torpid—the bowels constipated. To meet this condition Dr. Chase worked out the treatment now so well known as Dr. Chase's Kidney-Liver Pills.

This treatment was long tested in private practice before it was given to the public. Time has proven that the old doctor was thorough in his work, for there are many thousands of people ready to certify that there never was a real rival to this standard medicine.

If more people realized the effectiveness of this treatment, there would be fewer operations for appendicitis, peritonitis, gall stones and other deadly ills, which are certainly caused by neglect to keep the filtering and excretory systems in healthful condition.

Let the Dr. Chase Plan of Health be your guide and you will add years of health and comfort to your life. If you are not familiar with Dr. Chase's Kidney-Liver Pills, just mention the Maritime Farmer and we shall send you a sample box free of charge. One pill a dose, 25 cts. a box, at all dealers, or Edmanson, Bates & Co. Limited, Toronto.

DETECTING CHOICE LAYERS

My wife called my attention one day to the pelvic bone test for detecting choice layers. She had forgotten just where she received the information, but thinks that it was probably in one of the farm papers. I have followed the test carefully since, and I am greatly convinced of its importance. I am giving it here because I believe all keepers of chickens should know the test.

To apply the test measure the width between the horns of the pelvic bones with the fingers. If three fingers will lie easily between the horns the hen is in all likelihood a choice layer; if two fingers lie between the horns the hen may be a fair layer, but is assuredly not the best; if only one finger can be inserted between the horns the hen is a very poor layer, and should be culled from the flock.—E. V. L.

FOR GROWING DUCKLINGS

Growing ducklings thrive best on a feed composed of equal parts, by measure, of corn meal, ground peas, bran and middlings, all made into a thick mash, either with scalding hot water or milk, the latter being the best. The mash is improved by adding short-cut green stuff, and a few handfuls of coarse sand.

Timothy hay is not particularly high in feeding value but the fact that it can be fed with little waste and that practically all classes of live stock eat it readily makes it a general favorite on the market. It usually contains about 6 per cent. protein, 45 per cent. carbohydrates, 2.5 per cent. fat and 29 per cent. crude fibre.

FOR HOME AND COUNTRY

This Department will be utilized to the best interests of the homes in the Maritime Provinces. Subjects relating to household science and all that stands for better homes and communities will be published on this page. The editor, Mrs. M. A. MacLeod, Sussex, N. B., solicits your assistance in making this page a success and will be glad to publish tested recipes, household discoveries and other articles useful to the homemaker and women's or-ganizations.

THE TORCH

By Fanny Lea

"I don't think," said Mrs. Pennington slowly and with a controlled movement of dry, unwilling lips, "that you quite understand me."

Her husband looked back at her from across the hearth grimly, not caring to conceal his incredulous displeasure.

"I don't think," he assented chillingly, "that I do."

He folded the newspaper he had been reading and laid it down upon the library table with the unconscious method that was part of the man, then put cool finger tips together and inspected his wife deliberately through gold-rimmed eye-glasses, as if she had been some new and undesirable kind of visitor.

"What," he asked finally, "are you talking about? Do you know, yourself?"

"Quite well," Mrs. Pennington answered without resentment. "I know quite well what I am talking about. Do you want me to say it all again? Is that necessary?"

Her tired blue eyes, faded somewhat grayly from their first clearness, yet gave back his look with an undaunted purpose, and the soft, indecisive mouth set itself in sterner lines. In the lap of her quiet, neutral-colored gown, her little roughened hands folded themselves tightly, asking strength from each other.

"Shall I tell you again?" she insisted with a kind of gentle stubbornness.

Mr. Pennington's answer was the exaggeration of courtesy. "If you will be so good."

Mrs. Pennington drew a long breath and her muscles grew tense. "I want to go away," she said doggedly; "that is all there is to it. I want to go away."

"You mean, I suppose, a visit to some of your people."

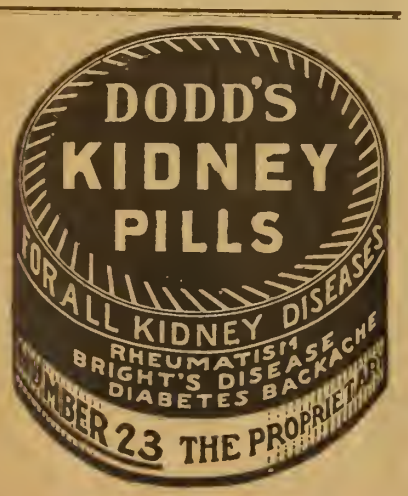
She shook her head, setting her teeth on her lips' unsteady treachery.

"I want to leave you—you know what I mean."

"I do not," Mr. Pennington denied with some irritation. "I have not the remotest idea, Louisa—and that phrase has a very unpleasant significance. Please do not use it again. It is generally associated wtih scandals and the divorce court."

"But that is what I mean," Mrs. Pennington persisted. "I want a separation."

She did not lift her eyes from the cheerful fire in the grate until the burden of silence frightened her and set little frightened pulses twitching in throat and brow.



"That is what I mean," she repeated bravely, and looked across into her husband's startled face.

He sat aghast, regarding her, speechless, chill eyes lit with a flame of incredulity, thin mouth weakening to an unuttered exclamation. While their glances crossed, a dull, angry red rose to his brow and suffused the roots of his scant, dark hair.

Twice he opened his mouth, and snapped it shut, with a futility of expression that woke a mad desire for laughter in the woman before him, evolving inadequate speech at last in a voice keyed curiously higher than his wont.

"Well," he jerked out baldly, "upon my word!"

Mrs. Pennington waited in silence for a more definite answer. She did not look like a woman to fight her way out of the rut, but her eyes were very steady, and they did not fall before the man's dazed, furious look.

He pulled himself together presently with an obvious effort, stiffening his face to its accustomed, controlled mask, and settling his glasses with a hand that shook slightly.

"So you want a—a separation?" he observed, failing a little in his endeavor of toneless detachment. There was amazement and a throbbing anger in his voice.

"You have a reason, I suppose, for this remarkable statement?"

"Yes," she said quietly, "yes—I have a great many reasons, Mr. Pennington."

"I should like," he demanded, "to hear one of them—one of these amazing reasons of yours—that would justify such an appalling step."

In the firelight, that showed pitifully plain the little lines about her eyes and the deep,strained furrows on either side of her mouth, Mrs. Pennington essayed to smile.

"If you will only not look at it in that way," she said with an incongruous gentleness. "I have no wish to affront you or hurt you. This is not a crazy impulse on my part; it is an old determination. There are a great many things that—that are concerned in it."

"A great many— Oh talk sense!" said Mr. Pennington brusquely. "I should like to get to the bottom of this, if you please." He beat an intolerant tattoo with the knuckles of one hand upon the palm of the other.

"You would have a long way to go," answered his wife slowly, "but I think I can tell you—if you will let me. There is no reason, is there, why we shouldn't talk it over impartially?"

Mr. Pennington leaned back in his chair, gripping the arms of it with wiry, nervous hands. He stared gloomily into the fire with unbelieving eyes.

"Go on," he commanded, "for God's sake! After twenty years—this melodrama!"

The woman's clasped hands tightened breathlessly, every muscle of her body rallying to the strain she had set upon herself.

"This melodrama, as you choose to call it"—she struck the first note of resentment—"is nothing new. Only, you haven't seen it before. It had a beginning seventeen years ago. You remember Dorothy's first birthday?"

"I remember nothing."

"Then I can tell you. The night of Dorothy's first birthday—we had been married three years—we quarrelled—do you remember now?"

She waited a moment, but he did not answer.

"I don't mean that the quarrel was everything. It was only the—the culmination. It was a small thing, perhaps, but it came after a great many other small things—"

She fumbled a moment carefully for words, her inner consciousness a pitiful blur of struggling days and anguished nights. "It came after a great many other small things," she repeated, as if to gain time, groping her way cautiously.

"It is incredible," Mr. Pennington began angrily yet with a sort of dazed endeavor to follow. She interrupted him swiftly.

"If I were a witness, you'd let me tell what I knew. You can listen to other evidence—why not to mine? It's not easy for me to explain—" She broke off to begin again more calmly.

"I was very young, you know, when you married me, and very sensitive. I didn't know then a great many things that I have learned since. I thought the world was just what it looked like always, and what the poets and musicians and painters had made it out to be. I had been kept carefully all my life inside a fence, where horrible things and wicked things"—she flung out the next phrase desperately—"and true things—were not allowed to come. All I knew of life I had gotten from silly novels and poems where the wedding bells are the end of the story, and marriage is never for anything else but love. Perhaps that made me stupid and slow to understand, but you were not too patient with me. It used to seem sometimes as if you didn't care, having once gotten me for your wife, whether you kept my—my love—or not. I was just a fact in your life, like the breakfast table or the evening paper. You didn't have to win me; I was there—just a matter of course, like everything else in the house—fires and meals and furniture."

Mr. Pennington moved and frowned irritably.

"This is the sheerest sentimentality," he said. "I asked for a reason."

"I am trying to show you," she defended, not yielding an inch, though a slow, painful flush belied her control. "Can't you see what a difference there was in everything to me? I had been poetic and idealistic and—foolish. Life meant a thing to be softened and made beautiful and uplifted. When you said—when you asked me to marry you, I cried half the night for happiness, and I prayed—prayed, mind you—beside my bed, with my face hidden, that I might make myself what you believed and wanted me to be. Well, I have been a good housekeeper—I suppose my prayer was answered."

She hurried on before his impatient protest.

"What I mean is that I married you, expecting things that never happened. And others that did happen I had not dreamed of. Most people are like that, I suppose; but when they love each other it's worth while—they can stand the mistakes and the clashes. You didn't care for me—after you married me—enough to smooth things over. And you were always clever; there was nothing too bitter for you to say to me when I failed to meet your requirements."

"You spoke of a quarrel," said Mr. Pennington coldly. "This other, I imagine, is every man's and every woman's experience. A woman can always see a tragedy in the commonplace, so long as it concerns herself."

His wife did not look at him. She waited a moment, seeing in a dim, visioned space those earlier days of sordid disillusion—her hopeless wrestling for adjustment of Life and the Dream.

"I don't know," she said at last quietly, "whether you will see any better when I remind you of the quarrel. I told you it was nothing of consequence to you. We had been talking of something you wished me to do—there was a business man in town who could be of use to you, and you wanted me to call on his wife. I was timid, foolishly, of course, and I didn't want to go. Do you remember the discussion?"

"Not in the least," he denied grimly. "I must say it all seems very absurd to me. I may be prejudiced."

"You said," she prompted carefully, "that you had expected me to be a help, not a hindrance. You were very angry about it. You said that you were sick of my childishness—that you had stood a great deal of it—and that, apparently, I realized no obligation whatsoever. You asked me at last, after a great many other unkind things, what I supposed you had married me for."

She stopped with a little breathless catch in her voice, then went on again, always quietly, even with a sort of detached exactness.

"I said for love, I supposed—and you laughed. That was very nearly unpardonable. Then you lighted a cigar, I remember quite distinctly, and as you threw the match away you said"—she quoted clearly—"'Don't be absurd! You talk like a schoolgirl. There are bigger things in the world than sentiment. Of course, a man's affection for his wife is always a consideration, but in sheer justice there are certain other things she owes him in return for his name and support: the care of his home, and so on. That's common sense. All love is material—to be ab-

HAD SEVERE PAINS IN SIDES AND BACK.

HAD TO GO TO BED.

Women are the greatest sufferers from weak, lame and aching backs owing to the continual stooping, bending and lifting so necessary to perform their household duties.

Women should not despair even if they are troubled with severe pains in the side or back, and not able to attend to these duties, as all they need to do to make the back strong and well again is to stimulate the kidneys with Doan's Kidney Pills.

Mrs. John Simmons, Coleman, P.E.I., writes: "I feel it my duty to recommend Doan's Kidney Pills to any one having weak kidneys, as they have been of great help to me.

Some time ago my kidneys were so bad I had severe pains in my sides and back, and it was impossible for me to stand straight. I then got so bad I had to go to bed, and was that way for a week. I sent for some Doan's Kidney Pills, and I took just about one box, and was able to get up and do my own work."

Doan's Kidney Pills are 50c. a box at all dealers or mailed direct on receipt of price by The T. Milburn Co., Limited, Toronto, Ont.

solutely frank about it. Marriage involves so much for so much. You ought to have sense enough to know that—' "

He would have interrupted now, but she silenced him with one out-thrust hand. Memory came back to him slowly. She saw it in his changing face—at the sound of those unlovely words drawn up before him, the ghosts of a long dead anger.

"Oh, I know you were infuriated. You said more than you meant to, perhaps. I had irritated you. But even so, no circumstances under heaven—Can't you see? Can't you? Can't you see it was like the end of everything for me? You had taken everything I had to give, and you considered that you were paying for it with your name and support! You degraded me—unspeakably. But it made things plain to me—the horrible mistake I had made. I couldn't love you after that. You had better have struck me in the face."

"Absurd!" he muttered.

"Not so very absurd, after all," said little Mrs. Pennington gently. "A girl who isn't very old and hasn't had very many lovers is easily mistaken, I suppose. There are so many things that look like love—how is she to know, until her hands are tied? But once she knows the mistake, she can never go back."

She hurried a little before the impotent scorn of his look. "It had seemed a very fine thing to be loved, to be engaged. I was proud of you, and of your good looks—and your success. I was proud of myself because you wanted me. I was not so proud when I learned the truth. It was not me that you wanted—especially, only a wife. It happened that I came in your way just then.

"Anyhow"—she stumbled, losing her control a little before the cold reproach of his eyes—"I made a mistake. I should never have known it if you hadn't shown me. I wanted to go back to my mother, then, but Dorothy cried in the next room, and she was only a baby—my baby—so I stayed. I couldn't leave her, and I knew you wouldn't let me take her away. I didn't say anything more to you, but that night, after I had cried myself still, I made myself a promise—that I would leave you as soon as Dorothy should be old enough not to need me. I saved my self-respect that way."

She stopped, twisting a handkerchief drawn from her belt between chill, nervous fingers.

"Dorothy was eighteen last week—and I am not going to wait any longer. I have waited seventeen years already; that is quite a long time, you see."

"I see," said Mr. Pennington drily, when she had done. "You have endured your married life for twenty years, and at this late date it becomes intolerable to you. That is very strange."

"Not strange at all," she insisted, pitifully firm. "You don't seem to understand. I have endured it because I meant to free myself in the end. I did it for Dorothy—can't you see? She has never known that there was anything wrong. A child has to have its ideals to begin on, and Dorothy has had hers intact—I've seen to that. She hasn't guessed that there was ever anything wrong. She doesn't know that there is not the most perfect sympathy between us. A child is at such a horrible disadvantage when its parents are—when they do not agree. I have saved her that."

She strained her clenched fingers against each other, and looked at him almost pleadingly.

"I am not hating you for it," she explained hopelessly. "I am not even reproaching you. But don't you think when I tell you that I have waited seventeen years for Dorothy's sake—that for seventeen years I have wanted to be free—don't you think you might let me go—quietly?"

Her hushed, earnest voice sounded distinctly through the still warm room, above the little homelike noises of dropping coals and the clock ticking on the mantel.

"I do not suppose," said Mr. Pennington carefully, "that any man was ever forced to listen to such a diatribe before."

"There are a great many things," Mrs. Pennington replied with a wistful, unconscious humor, "that men are not forced to listen to—when they

Suffered Great Agony.

Pains in the Stomach For Over Three Years.

Miss Dorothy Clark, Kouchibouguac, N.B., writes: "For over three years I suffered great agony from pains in the stomach. I tried several remedies, but got no relief until a friend advised me to take Milburn's Laxa-Liver Pills. I started with two vials, and before I had one quite used I found much relief. I continued until I used four vials, and they have completely cured me. That was fourteen months ago, and I have not had the slightest return since. The best praise I can give them is not enough."

Most of the misery and ill-health that humanity is burdened with arise from disorders of the stomach, liver and bowels. If you are feeling out of sorts, have pains in the stomach, especially after eating, bilious spells, headaches, sour stomach, coated tongue, water brash, etc., you should take a few doses of Milburn's Laxa-Liver Pills. You will be surprised how quickly they will fix you up."

Milburn's Laxa-Liver Pills are 25c. a vial at all dealers or mailed direct on receipt of price by The T. Milburn Co., Limited, Toronto, Ont.

should be. I'm sorry."

"Sorry!" he retorted contemptuously. "I am amazed—absolutely amazed! After all this time—do you expect me to believe that you have had this thing in your mind for seventeen years?"

"I have just told you so."

"Seventeen years, in which you have kept my house, brought up my child and borne my name—without a protest."

Address

MRS. M. SUMMERS, Box 309
Windsor, Ont.

"The laborer," Mrs. Pennington defended, "is worthy of his hire. I have earned my keep, I think."

"That is not," said Mr. Pennington disgustedly, "a very refined nor edifying way of expressing it."

Mrs. Pennington smiled with difficulty, and a little wryly. "You are inconsistent," she objected softly. "It is not, to my mind, a very refined or edifying thing to express, but you taught it to me yourself."

They looked at each other a moment in silence, measuring swords, as it almost seemed, and the man's look wavered first. He shifted in his chair and turned eyes of concentrated bitterness upon the flame.

"You did not expect the moonshine to outlast the first twelve-month?" he offered, something in his tone and look nearing a compromise. "I thought you had better sense. Marriage is a sensible, ordinary institution for everyday people—not a romance."

"I know what marriage is now," she said very quietly.

"I have not stinted you in money, clothes, things about the house."

"You have paid your bills," she agreed. "They were not overdrawn."

He faced her suddenly, his mouth working, his control sapped by her dogged resistance.

"You have seemed to be satisfied," he broke out huskily. "You have not objected to me and my ways. We have lived very peaceably together—"

"Because you have had your will in everything."

"Whatever the reason, we have lived peaceably. In heaven's name, what possesses you now? You have kept quiet all these years—"

"That was for Dorothy," she reiterated, steadfastly returning his look.

Presently he got to his feet and paced the floor, lashed by a resistless realization of the will beneath her gentle surface. She sat still, looking into the fire and waiting.

"You have no right to ask this thing," he said at last, halting beside the table. "I suppose you know that."

"Then I shall not ask it," she replied stubbornly. "I shall simply tell you what I am going to do."

He took up his restless stride again, flinging over his shoulder a barbed shaft that struck and quivered in the wound is made.

"What about Dorothy now?"

Dorothy's mother went white after a very ghastly fashion, drawing the back of her hand across eyes that strove to see clearly.

"It is selfish of me," she said after a little—"do you thing I don't know?—horribly selfish. You can tell me nothing like that that I have not seen. I do not for a moment defend myself"—the slow voice trembled—"but I cannot change. I have a right to something out of my life, and I am going to have it. Dorothy is a woman now. And she need not learn the truth all at once. I can go away, and she must gradually realize that I am not coming back. When she was born I was no older than Dorothy is today. She is old enough to understand. I have not been selfish all my life, but all my life I have been unhappy. Now, I am going to try the other way. I know what I am doing. You cannot stop me."

"It makes no difference, I suppose, that you will be giving her name to the public for a football?"

"Hardly that," said Mrs. Pennington with a tired little movement of one hand. "It isn't uncommon nowadays for women to leave their husbands. I'm afraid I can't change. You see, I have been waiting such a long time."

Mr. Pennington came back to the fireplace and stood there, frowning coldly.

"If I could see your point of view," he began, "I might hope to understand you. As it is, I can make nothing out of your explanation beyond the fact that seventeen years ago, by way of an absurd and trivial dispute, you found that you did not—er—care for me, and, as a result, you wish to leave me now. Why, I cannot see. I do not ask any youthful absurdities in the

matter of emotion. A calm, unexacting affection is all that is expected of people of your age and mine. As I said before, we are past the time of moonshine, my dear"—he frowned, because she winced at that—"and, to the best of my knowledge, in these last seventeen years which figure so conspicuously in your remarks, we have been very comfortable."

Mr. Pennington ceased. He had once been referred to as the coolest, most level-headed lawyer in his town, and he was apt in didactic movements to be sustained by the remembrance. He was therefore the more startled and discomfited by the flame that lighted his wife's face beneath his eyes of scorn, and white, despairing rage.

She slipped to her feet and stood by the table, one hand on its green-covered surface, the other at her trembling throat.

"Comfortable!" she cried almost in a whisper. "Comfortable!"

He stirred uneasily beneath the flick of her contempt.

"Yo uthink it is comfortable to find out at nineteen that you have married a man who does not love you—and live with him till you are thirty-six? I was sixteen when I married you—a child, that's all, just a child. And you have had all the best part of my life. What have I had? Nothing. What am I going to have? Myself. I'm not an old woman yet. I can go away and have a little house somewhere and work and sleep and rest—by myself. There are hundreds of books I have never read, and there's music I've never heard—I shan't be lonely. And I can be honest. I'm so tired of pretending. I've been pretending for seventeen years."

It seemed incredible, in the accustomed quiet of the room, among all the familiar objects, with the paraphernalia of every day about her, that the little white-faced woman could change so suddenly and so vitally to a creature of flaming purpose. She would not even let him speak.

"I don't know," she said unevenly, "why girls aren't told the truth about things. My mother would have given her life for me—but she let me marry you, thinking love was the reason of everything. I had a world of pretty ideals—bubbles, that's all—and she never explained to me that I couldn't keep them. That's why it hurt so to have them broken. Isn't it strange—this thing of a girl's ideals? They're like a torch, the mother keeps burning for the daughter—the mother, who no longer herself believes in them. The torch is handed down from generation to generation—and in sptie of it all the truth is always there, the truth that has got to be learned. If only they didn't teach us to expect so much, the disappointment would be easier."

She caught her breath sharply. "Anyhow, I can't pretend any longer—I'm too tired. I promised myself I'd be free—and I will. You mean nothing to me—less than nothing; and the whole world is welcome to know it!"

Her voice rose a little, shrilling above its soft, slow pitch, through unsteady lips that could not now control it.

"Hush!" said Mr. Pennington uneasily. He laid a hand on her arm, but she shook it off at once. "You are not yourself; you are hysterical."

"Is it any wonder?" She held herself fiercely quiet with the clasping hand at her throat, steadying herself against the table. "There are times when I have felt as if I should scream it out to the people in the street—as if I didn't know the man whom I had married at all—as if I had waked up some morning to find myself owned, body and soul, in the house of a stranger—"

"Sh-h!" said Mr. Pennington again. A look of nervous concern displaced the impassivity of his features. He drew a breath, almost of relief at this simplfying of the situation. Feminine hysterics he could at least recognize and categorize.

"Don't you think you'd better go to bed? You're all unstrung. I dare say you're run down, and your nerves are bad. You'll think better of this in the morning. I'll get Barton to give you a tonic. We won't talk any more tonight."

Mrs. Pennington controlled herself with a wrenching effect and turned away.

"You're right," she said wearily; "we won't talk any more tonight. I don't think I could stand it. But will you please think over what I've said I'm not hysterical; I mean it."

"You'll change your mind," said Pennington soothingly. He followed her to the door, humoring her with a magnanimous appreciation of his own handling of the situation.

"You're nervous now and upset. I reproach myself for not having seen before that you were not well. I may have lost my temper and irritated you—but this is all a mistake. You'll change your mind."

"No," said Mrs. Pennington slowly, "I thnik not." She looked at him, and was disheartened by the uncomprehending indulgence in his face.

"It's no use," she murmured. "Please don't come any farther. Good night."

When she had gone a bare step or two away she turned back again, her look incredulous.

"You can't possibly mean that you would want me to stay after what I have told you?"

"I know that you are not well," he answered exasively, "and I make allowance for your nerves. We often say things in the heat of the moment—"

"So that is the way you prefer to put it!" She shook her head, her tired eyes giving him the lie direct. "In the heat of the moment one might, perhaps; not in the heat of seventeen years!"

From the landing of the stairway she looked down at him. He stood in the door, head bent, one nervous hand fumbling with his glasses, and while she watched he turned and went back into the library. She heard his chair drawn slowly to the hearth and the scrape of a lighting match.

Mrs. Pennington went on up the stairs and into her room at the end of the upper hall. There was a sudden and satisfying sense of achievement at her heart, although her hands were cold and her limbs quivered with the last surges of the emotion which had overswept her. While she undressed and let down the braids of her heavy, straight brown hair, her mnid brooded over its new freedom with an access of exultation. After seventeen years she had spoken the truth; and tomorrow she would go away, possessing herself again. She had been strong to wait, and she would be strong in the fulfillment of her desire. Only to be alone, to be free, to be herself—that was little to ask of life. And there was no one who would be harmed by what she did. Her freedom would react on no one's happiness. The man she called her husband had grown used to her presence in his house. He would as easily grow used to her absence. She owed him nothing—nothing but what she had paid—much unhappiness she had not paid. Dorothy—she would not think of Dorothy—she dared not. She swept the straight darkness of her hair down on either side of her face and brushed it lingeringly before the mirror. Her eyes looked back at her, clear but a little faded—they had been blue as gentians once. Above the straight prim collor of her brown flannel dressing gown her neck showed overly slender, with betraying cords. Those lines about her mouth told the story of hot words bitten back, and a tired need for laughter. A rush of stinging tears misted her sight, for sheer pity of the eager girl's face that no longer looked back to her from the mirror.

She had asked so much of life, that girl, and she had had so little.

Out of the half-twilight behind her in the glass, a slim, small figure took gradual shape and blossomed. Wide blue eyes under a soft sweep of hair and a low white brow, a mouth that curved to a confident sweetness, cheeks carnationed, even in the shadow—Mrs. Pennington stared back at the girl face dumbly, drawing her hand across her eyes, her lips tremulous. It was the face her mirror used to yield her, but while she looked it rippled to a smile, and with a sweep of white silken skirts Dorothy crossed the room and stood behind her mother's chair.

"What are you looking at, darling?" she teased, linking bare white arms about her mother's neck. "Did you think I was a ghost?"

Mrs. Pennington shook her head. "You startled me," she said quietly, "only for a moment. Aren't you late coming up, Dolly? Has Mr. Hazelhurst just gone?"

"Only just," Dorothy answered with a quick little movement of embarrassment. "Let me brush your hair, mother—do. Give me the brush."

She bent her head above the brown, soft strands. "You have such pretty hair. It's much longer than mine—mother, dear."

"Yes?" said Mrs. Pennington abstractedly. She leaned back in her chair, relaxing wearily to the soft, regular sweep of the brush.

"When you were—that is—when you and father were first engaged," said Dorothy slyly after a little, "how old were you?"

"Sixteen. I was almost seventeen when we were married," her mother answered perfunctorily. Then some sympathetic current arrested her sharply. "Why?"

"Nothing." Dorothy protested. "Oh, nothing! He had only a small salary, hadn't he? I've heard him say so."

The face above the swiftly moving hands flamed radiantly crimson, and the blue eyes shone through a happy mist.

A SALAD HINT

Sprinkle a little sugar or a little salt over apples which are to be used in salad, and they will remain white instead of turning brown. In this way the salad may be mixed some time beofre it is to be used.

I KNOW A WOMAN'S SUFFERINGS

I am a woman.
What I have suffered is a far better guide than any MAN'S experience gained second-hand.
I know your need for sympathy and health.
And the treatment that gave me health and strength, new interest in life, I want to pass on to you, that you, too, may enjoy the priceless boon of health.
Are you unhappy, unfit for your duties? Write and tell me how you feel and I will send you ten days' FREE trial of a home treatment to meet your individual needs, together with references to women in Canada who have passed through your troubles and regained health; or you can secure this FREE treatment for your daughter, sister or mother.
If you suffer from pain in the head, back, or bowels, feeling of weight aud dragging down sensations, falling or displacement of internal organs, bladder irritation with frequent urination, obstinate constipation or piles, pain in the sides regularly or irregularly, bloating, dyspepsia, extreme nervousness, depressed spirits, melancholy, desire to cry, fear of something evil about to happen, creeping feeling up the spine, palpitation, hot flashes, weariness, sallow complexion, with dark circles under the eyes, pain in the left breast or a general feeling that life is not worth living, I invite you to send to-day for my complete ten days' treatment entirely free and postpaid, to prove to yourself that these ailments can be easily and surely overcome at your own home, without the expense of hospital treatment, or the dangers of an operation. Women everywhere are escaping the surgeon's knife by knowing of my simple method of home treatment, and when you have been benefited, my sister, I shall only ask you to pass the good word along to some other sufferer. My home treatment is for all,—young or old.

Read My FREE Offer:

To Mothers of Daughters, I will explain a simple home treatment which speedily and effectually dispels green-sickness (chlorosis), irregularities, headaches and lassitude in young women, and restores them to plumpness and health. Tell me if you are worried about your daughter. Remember it costs you nothing to give my method of home treatment a complete ten day trial, and if you wish to continue, it costs only a few cents a week to do so, and it does not interfere with one's daily work. Is health worth asking for? Write for the free treatment suited to your needs, and I will send it in plain wrapper by return mail. Cut out this offer, mark the places that tell your feelings, and return to me. Write and ask for the free treatment to-day, as you may not see this offer again. Address:

MRS. M. SUMMERS, Box 309 Windsor, Ontario

THE CHILD WHO CONTRADICTS

"I have a little girl just past seven, who is very bad about talking back and being contradictory. I have tried to break her of the habit, but she seems to be growing worse instead of better, and she is usually cranky, gets up that way in the morning, and comlains and growls all day, especially when things don't go just as she wants them to."

There must be something wrong with either the nutrition or the sleeping of your seven-year-old daughter if she is "cranky" most of the time, and gets up in the morning complaining and growling. Seven-year-old children who are in vigorous health do not behave in this way. Do Dyou know whether she is in good physical condition? Does she sleep soundly? Does she have adenoids which stop up breathing passages and interfere with her sleeping and with her breathing while she is awake? Does she have enlarged tonsils? Are her teeth sound Are there some teeth that are not yet cut, and so may be pressing upon nerves and making her irritable and "cranky"? If she has always been inclined to complain and growl, you cannot lay the cause to the teeth, but adenoids or enlarged tonsils might be the cause.

Does she eat a good deal of sugar, or candy, or honey? I presume you do not give her any tea or coffee or much cocoa. If you do, this may explain her irritability. Does she like fruit? Is she notional about her eating, or will she eat the usual articles of food with a good appetite? Does she have some food with bran in it, either in the form of bread or cereals? Most children need a little rough food every day. I suppose you do not give her much meat. Meat makes most children irritable. Does she eliminate thoroughly This is absolutely necessary in order to avoid irritability.

If the child is well physically, and sleeps restfully, and still complains constantly, perahps it is because she is nagged a good deal. If the moment she gets up in the morning somebody begins complaining about her conduct, then aturally she will react in the same way. You say she "talks back and contradicts.' This suggests that you command her a good deal and argue with her. It is not unusual for children who are bossed constantly to talk back. Most childrei of the age of seven years do not give in readily to a parent or anyone else wha nags them. If you will watch yourself you will probably discover thav yoh do not give in readily. You contradict your child though you are not apt to think of it in this way.

The best way to deal with talking back and contradicting is not to give the child an occasion to do it. Par ents generally argue too much with their children, and incite them to be contradictory. The less arguing the better with any child. If certain things must be done, get them done without talking. It would be well if you would watch yourself ti see whether you do not unconsciously arouse your child to take the defensive. Many parents like to have their own way and can not stand it if a child asserts his individuality.

HAYING SEASON

Some town folks think that labor-saving devices have driven hard work from the farm. But, while the hay loader and the hay unloader, the self-binder and the separator, and all the machines of modern farm life have lightened toil, there is still enough of it left—and more than enough for most farmers.

Farming has its attractions, but at its best, it is a well man's job.

Away back in the sixties, in the strenuous days when this country was in the making, when scythes and sickles were still in use, Dr. Chase devoted himself to keeping men and women strong, to rendering them capable of performing a long day's work with the least possible fatigue. And therein lies the secret of the PERMANENCY of his success. Fifty years have gone, a half century crowded with innovations, and through all this time Dr. Chase's Remedies have retained their usefulness.

The mechanical engineer and the skilled physician have each in their way contributed to the happiness of mankind; one by reducing labor, and the other by keeping mankind fit for labor. Unfortunately the labor-saving devices of the engineer are not within every hay maker's reach. All mows are not equipped with horse-lifted forks or slings, and if they were, strong backs and steady, untiring arms would still be required in meadow and mow. In these strenuous days when men and women are called upon to do an unusual amount of work, when many—especially women—are obliged to do unusual work, there is a greater need than ever before of making provision for health.

Hard work effects the breaking down of myriads of cells in the human body. These cells when broken down, become so much ash—so much waste matter—which left in the blood poison the system. It is this poisonous waste matter in the blood which makes you feel completely tired out after a hard day's work.

The kidneys were designed by nature to filter these poisons from the blood and they must be kept healthy and in good working order. This is just where Dr. Chase's Kidney-Liver Pills befriend every man and every woman with hard work to do.

You can't pitch hay or do other heavy farm work with a lame, weak, aching back, and the quickest way to get the back right is by regulating the kidneys with Dr. Chase's Kidney-Liver Pills. You can buy them at any place where medicines are sold at 25c a box or by mail from Edmanson, Bates & Co., Ltd., Toronto. Why not let the Dr. Chase Plan of Health help you through the hard work this season?

Dr. Chase's Kidney-Liver Pills, one pill a dose, 25c. a box at all dealers or Edmanson, Bates & Co., Ltd., Toronto

SIMPLE RULES FOR THE USE OF FATS

The appeal of the Food Board to reduce the use of fats, and especially to limit butter to free use on the table rather than in cookery, is important.

To meet the needs of the country and do our part in the Home Army in the kitchen, these definite rules in regard to the use of fat will be helpful.

Breads:—Fats may be omitted entirely if desired.

Use clarified pork or beef fat, hardened vegetable fats, fat compounds.

Hot Breads: as Biscuits, Muffins, Pancakes:—Use clarified pork or beef fat, hardened vegetable fats, fat compounds, sour cream.

Cakes: as Cookies, Cup, Chocolate, Spice, Ginger:—Use clarfiied beef fat, chicken fat, pork rat, hardened vegetable fats, fat compounds, sour cream, grated chocolate.

Puddings:—Use clarified beef fat, chicken fat, sour cream, chopped suet.

Pastry:—If pastry is used, let it be plain, not rich.

Use hardened vegetable fats, fat compounds.

Sauteing:.Use vegetable oils, clarified beef fat, pork fat, especially bacon fat, chicken fat, savory fats.

Deep frying:—Use oils, fat compounds, clarified beef fat, pork fat, mutton fat, combined with other fats.

But save fats by doing as little frying as possible.

To clarify:—Heat any sweet drippings from beef, pork, mutton, with boiling water, stirring constantly. When the fat and water has boiled freely, set aside dish to cool. Remove cold fat and again heat to drive out all water. Put in crock for use.

Savory fats:—Any fat warmed with a leaf of summer savory and a clove of garlic may be used in sauteing potatoes, hominy, rine.

Soap fats:—Fats which can no longer be used for deep frying, left-over fats, which are not quite sweet, may be put in a crock to save for fall soap-

Spanking Doesn't Cure!

Don't think children can be cured of bedwetting by spanking them. The trouble is constitutional, the child cannot help it. I will send **FREE** to any mother my successful home treatment, with full instructions. If your children trouble you in this way, send no money, but write me to-day. My treatment is highly recommended to adults troubled with urine difficulties by day or night. Address

Mrs. M. Summers
BOX 309 WINDSOR, Ontario

making for home cleaning.

Recipe.—Dissolve 1 can of lye in 1 quart of water; cool. Add 6 pounds of fat, melted but not hot. Stir until white. Pour into pan and cut into squares as it harden. Let it dry thoroughly before using.

Note.—If the soap is to be white the fat must be clarified.

SAVES THE WINDOW CURTAINS

All housewives have experienced the difficulty of keeping muslin curtains from blowing against dusty screens or out on the roof when the windows are raised. Here is the way to solve the difficulty.

I sewed one-half of a garment snapper to teach of the lower outside corners of the hem on the wrong side where it will not show, and the other half of each snapper to the upper outside edges of the curtain about six inches from the top of the curtain.

At night it is an easy matter to snap the hem into these upper fastenings, and the curtains are held out of wind and weather without being crumpled.

CANNING BEETS WITH VINEGAR OR WITHOUT

Clean beets well, leaving two inches of stalk, and then blanche for 10 minutes in boiling water. Then dip them in cold water and remove the skin and stalks. Fill the jars with the beets, flat side down. Pour boiling water over them, adding 1 teaspoonful of salt to 1 quart of water, and put on the lids. Place the jars in a boiler of cold water, put on the cover, and boil for one hour, or until tender. Test with a knitting needle. Remove from the boiler and seal tight.

The same method is used for canning beets with vinegar, except that 1 part of vinegar is used to 4 parts of boiling water. The vinegar may be cold.

SALTED STRING BEANS

Grandmother washed and prepared string beans as for cooking, spread a layer of common salt in a big stone crock, jar, or wooden bucket (using anything except tin), spread a layer of beans upon this salt, and continued the alternate layers of salt and beans until near the top. Then she inverted a plate over the contents and placed a weight on the plate. Her rule was 1 pound of salt to 3 pounds string beans and no water. The beans kept indefinitely and when soaked a while before cooking, tasted like fresh-grown vegetables. Carrots, parsnips, artichokes, etc., were similarly kept.

TO CAN SPINACH OR KALE

Wash the spinach thoroughly through many waters; allow 1 cupful of boiling water to each peck of spinach. Cook until tender, skim spincah from the water and place in jars which have been previously sterilized, packing stolidly. Adjust the rubbers, strain the spinach water through a piece of fine linen, reheat to the boiling point and fill each jar with it to overflowing. Put the lid on, let the jars cook in water 10 minutes after the boiling begins, then tighten the lids. Kale is canned in the same way.

SWEET GRASS BASKETS

Baskets made of sweet grass may be kept clean by carefully wiping them with a damp cloth. The dampness also brings out a delightful fresh odor. This advice came from an Indian woman.

CANNED BEANS

Gather green tender beans, prepare as for boiling, put in a vessel with 1 cupful of salt dissolved in 3 quarts of water, and cook until about three-fourths done. Put into mason jars, seal tight, and put in a dark place in the cellar. To use, rinse and add fresh water, and cook until tender.

RHUBARB — COMBINED WITH OTHER FRUITS

With strawberries, I use 1 quart of finely cut rhubarb to 1 quart of berries. Cook the rhubarb in just enough water to prevent burning. When it begins to soften, add strawberries and half as much sugar as you have fruit. Cook slowly, stirring often until thickened; turn into jars. This makes a delicious strawberry jam at about half the usual cost. This same recipe may be used with other fruits.

HOW THEY PRESERVED CURRANTS IN 1850

Green currants were gathered when firm and large and put into black glass bottles, to keep away the light. The bottles were filled with fruit, no water, corked tightly, a bit of cloth tied over the top, and put in a dark cellar on their sides. When cooked they tasted much like Bar-le-Duc. Gooseberries and huckleberries may be bottled in the same way.

WILD RASPBERRY JAM

Wash the berries well, heat and boil for 15 minutes. Add three-fourths as much sugar as fruit and boil again for 15 minutes. Pour into small jars or glasses. When cold, cover with sugar to the depth of one-quarter inch, then with a layer of paper. Cover with a lid. These need not be sealed.

MONTREAL

THE PROVISION MARKET

There was no change in the Toronto market yesterday for live hogs and, according to advices received, there were no indications of any in the near future, prices being maintained, with sales at $19.75 per 100 lbs. weighed off cars, and at $19.50 fed and watered. The Winnipeg market was also reported steady, with the demand ample to absorb all offerings, and sales of selected lots were made at $19 per 100 lbs. weighed off cars. The domestic market today was firm, with trade fairly active in selected lots at $20.25 per 100 lbs. weighed off cars. The tone of the market for dressed hogs was also firm, with a fair amount of business passing in a wholesale jobbing way in abattoir fresh-killed stock at $29 to $29.50 per 100 lbs.

The condition of the market for smoked and cured meats was unchanged. A fair volume of business continues to be done in a wholesale jobbing way in most lines at firm prices, with supplies ample to meet all immediate requirements, and sales of 8 to 10-lb. hams were made at 37c to 38c per lb., 12 to 15 lbs. at 35c to 36c, and heavier weights at 34c to 35c. Breakfast bacon sold at 41c to 42c per lb., Windsor selected bacon at 45c to 46c, and Windsor boneless bacon at 48c to 50c. The demand for barreled pork continues slow and prices were nominally unchanged. American bean pork in car lots were quoted at $43 per barrel duty paid, clear short cut pork at $49, and clear cut back pork at $59.

A fair trade continues to be done in lard in a wholesale jobbing way, there being a steady demand for small lots to meet actual wants and prices were unchanged, with sales of Canadian pure leaf grades at 32c per lb. in 20-lb. wood pails, and at 33c. per lb. in 1-lb. blocks, white American compound lard sold at 27c to 27½c per lb. in 20-lb. wood pails.

THE LOCAL FLOUR MARKET

A very firm feeling prevails in the market for spring and winter wheat flour, but there was no actual change in prices to note. The demand for the Government standard spring wheat grade continues exceedingly good for both local and country account, and sales of car lots for shipment to country points were made at $10.95 per barrel in bags, f.o.b. Montreal, and at $11.05 delivered to city bakers. The trade in winter wheat flour was fair, there being a steady demand for broken lots to meet immediate requirements, and sales were made at $11.60 per barrel in new cotton bags, and at $11.30 in second-hand jute bags, ex-store. There were no new developments in the market for substitutes, prices being steady, with supplies ample to meet all actual wants, and a fair trade was done, with sales of broken lots of rye flour at $12.75 per barrel in bags, delivered to the trade; barley flour at $12.25, oat flour at $12, white corn flour at $12, Government standard corn flour at $10.70 to $10.80, and Graham flour at $11.05.

Millfeed and Rolled Oats

There were no new developments in the market for millfeed, prices for all

Have You Received Your Simpson Fall Catalogue?

If not, a Post Card will bring it to you

EVERY Season, thousands of homes throughout Canada eagerly look for the Simpson Catalogue. The new Fall and Winter Catalogue, just issued, is a magnificent production of 356 pages, illustrating almost every conceivable line of merchandise for personal and home use. It is larger and more complete than ever before—giving you fullest descriptions and life-like reproductions that make ordering a real pleasure. 64 pages are illustrated in the actual colors of the merchandise, so you can tell exactly the shading and the texture of the fabrics. Thousands of articles are shown in this catalogue—for personal and home needs it is especially complete—every member of the family may be satisfactorily suited.

Canada's Authoritative Style Book

Simpson's Catalogue is regarded by thousands of women as their guide to the latest styles and models, because the great organization behind the Simpson Catalogue makes it possible to offer the very newest styles in the most seasonable materials, at the lowest prices. Every member of the family finds something that he or she can buy cheaper and to better advantage through Simpson's Catalogue. Anyone having Fall shopping to do cannot afford to be without this book. Comparisons will show that the prices cannot be duplicated elsewhere. The Simpson Catalogue is a true guide to economy.

The Robert SIMPSON Company Limited
TORONTO

lines being firmly maintained, but the volume of business passing is not large on account of the steady increasing scarcity of some lines. Sales of feed cornmeal were made at $68, pure grain moullie at $67 to $68, barley feed at $63 to $64. mixed moullie at $55 per ton, including bags, delivered to the trade, and shorts were quoted at $40, and bran at $35. The condition of the market for rolled oats was unchanged. There continues to be a good enquiry for supplies, and a fair amount of business was done in broken lots of standard grades at $5.30 per bag of 90 lbs., golden cornmeal at $6.05 to $6.15, and bolted cornmeal at $4.25 to $4.50 per bag, delivered to the trade.

The Baled Hay Market

The tone of the market for baled hay continues strong owing to the somewhat limited supplies coming forward, and the good enquiry from all sources, but there was no further change in prices to note, sales of car lots of No. 1 hay being made at $18 to $19, No. 2 hay at $17, No. 3 hay at $15 to $16, and clover mixed hay at $11 to $12 per ton, ex-track.

Country Produce

There was no actual change in the condition of the local egg situation today, the tone of the market being still very firm, with an active business doing in a wholesale jobbing way, and in consequence supplies coming forward are not much in excess of the daily requirements, consequently the stock in store on spot during the months of August did not increase much, although the receipts for that month were larger than the corresponding one last year. The receipts of eggs for two days were 892 cases, as against 2,803 for the same two days last week, and 1,185 for the corresponding ones last year. The stock of cold storage eggs in store here on the first of the month shows an increase of 10,560 cases as compared with August 1st, and a decrease of 20,791 cases with September 1st, 1917. The stock of fresh eggs on the first of the month shows an increase of 49 cases as compared with last month, and a decrease of 2,446 cases with a year ago.

We quote wholesale prices as follows:

Selected new laid eggs.....51c to 52c
No. 1 stock.....47c to 48c
No. 2 stock.....45c to 46c

The tone of the market for honey remans firm and prices show no important change. The demand for supplies continues good and a fairly active trade was reported in a wholesale jobbing way, with sales of white clover in comb at 25c to 26c per section, white extracted in 30-lb. tins at 23c per lb., and buckwheat honey at 20c to 21c.

The market for potatoes was without any new feature to note. Supplies coming forward are ample to meet all immediate requirements and a good steady trade was done in small lots at $1.50 to $1.60 per bag of 90 lbs.

RAW EGGS CURE CALF DIARRHOEA

Diarrhoea is the most common form of calf troubles met with in hand-raised calves. As stated, much of it will be prevented by sanitary methods of handling the feeding pails, although it is occasionally met with in spite of all precautions. We have had a good many cases of this and have never lost a calf yet. We always begin treatment in the earliest stages of the disorder. We give two raw eggs as soon as the first symptoms of the trouble are noticed, and then one egg night and morning until the trouble is overcome. It might be supposed that if raw eggs will cure diarrhoea that too many would cause costiveness, but such is not the case. As soon as normal condition of the bowels is restored, the eggs have no further effect.

This treatment never fails if begun in time. If bowel troubles are not corrected at once, the passages soon become mixed with blood and the disorder assumes a form of dysentery. A cure after it reaches this stage is doubtful, but treatment is at times effective. Give corrosive sublimate, 7 grains in one pint of water, shaken well before each dose. One tablespoonful of this solution is given twice per day until cured. A druggist should always mxi this prescription. Corrosive sublimate is a deadly irritant poison, and extreme care must be exercised in its use. Calves suffering with bowel disorders must be kept warm and dry at any season of the year and not exposed to the weather.

MUZZLING A "ROBBER" LAMB

It often happens with twin lambs that for the first two or three days the stronger lamb gets practically all the milk, and the smaller continues to grow weaker. To enable the weaker lamb to get started it may be desirable to muzzle the stronger one for a few hours each day during the first week of their life.

Following is a simple way of doing it. A soft string is tied over the lamb's mouth, knotted just behind the ears, and is then brought down under the chin and again tied.—J. C. A.

HER ORDER

She checked the list with the greatest care. She said: "I think that it's all down there—a pound of tea and a box of soap, a bag of flour and a clothesline rope, two pairs of socks and a gingham dress, a laundry tub and a toy express. Then there's curtain rods and a window shade, a cut glass jug to hold lemonade, some kitchen spoons and a box of tacks, a spool of thread and a good strong ax. There's that silk dress length and the art sateen, a driving belt for my old machine, a pail of lard and a kit of pork, a poultry house and a stable fork. There's my winter coat and my hat, of course, those sheepskin mitts and that rocking-horse, a folding bed and a bunch of lace and a nickel watch and a radium face, some liver pills and a pound of glue. "My land!" she said, as she checked it through, "I've clean forgotten the paint and books, the mustard pot and the picture hooks, the frying pan and the dairy pail. It's great to order all these things by mail to shop at home in my easy chair, from my catalogue, when I've time to spare, to look it through for the things I need. It's a most convenient way indeed—on a list like mine they prepay the freight and they'll all arrive at an early date. The time it saves, and the bother too!" And she seemed so sure that I judged she knew!

The Power Behind Your Farm Work
Power is a dominant feature on your farm today. Equip yourself with an efficient power plant and your results are half assured.
A Fairbanks-Morse "Z" Engine
does the work of several men better and more economically.
150,000 farmers are daily demonstrating that the "Z" is the greatest engine value ever produced.
Get acquainted with it and save money. You will find it economical and easy to operate.
For pumping, lighting, sawing, cutting the feed —the "Z" Engine fills every want.

HOW TO CARE FOR WHEAT CROPS

(Continued from page 745)

soil gives you for your energy. See that there is no spurrious matter in your wheat bin.

You yourself hold in your own hands to a great extent, the destiny of the grain you grow. Never forget that it is possible to reduce ordinary sawdust to a fine flour-like dust and when building bins see that you sweep them out, don't mix the saw dust with the wheat. Cleaning machinery in the mill may handle a lot of the cleaning, **but never** expect to get one hundred pounds of product from that weight of wheat and iron and dirt and weed-seed.

With regard to the wheat itself, every farmer realizes the importance of choosing a good quality of seed. One which gives results and being clean, will grow a standard quality of grain. Many types of grain are used and it really does not interest the miller much which brand you have so long as it is reasonable in size and quality. By standardizing your wheat you standardize your flour and bran and shorts as to quality, texture and appearance. You cannot get good quality flour out of broken, shrunken wheat and screenings. Frozen wheat may be used in flouring btu really does not amount to anything worth considering, and do not expect the miller to do for you, that which you have not done for yourself. Remember always, that the average miller has pleased himself best when he has pleased you, and if he points out possible improvements, he fully realizes that these will reflect more to your benefit than his own.

CHARLOTTE COUNTY EXHIBITION

Attention is directed to the ad. appearing in this issue of the Charlotte County Exhibition to be held at St. Stephen, N. B., September 10-11-12-13. Always a big fair, the energetic board of directors are sparing no pains to make it this year, bigger and better than ever.

Large exhibits are assured in all departments and there will be instruction, as well as amusements, for all who attend. The mid-way at St. Stephen is always a live one, the free exhibitions the best that can be secured, and the Government displays this year will be very striking. Purses for horse racing amount to $2400 and all the speedy ones of the year are going to St. Stephen.

The Railroads are offering special rates to St. Stephen for the days of the big fair, September 10-11-12-13. A large number of tent shows have booked space for the mid-way and all popular forms of amusement will be on the grounds. Large list of entries have been received for the horse racing on each of the four days, and some of the best racing down east is assured.

Five troups of performers will furnish free vaudeville attractions each afternoo nand evening, and all who attend will find amusement and instruction well combined.

The St. Stephen fair is always a big and a bright one, and the show next week will be well worth attention.

BIG MERGER PONY FARMS

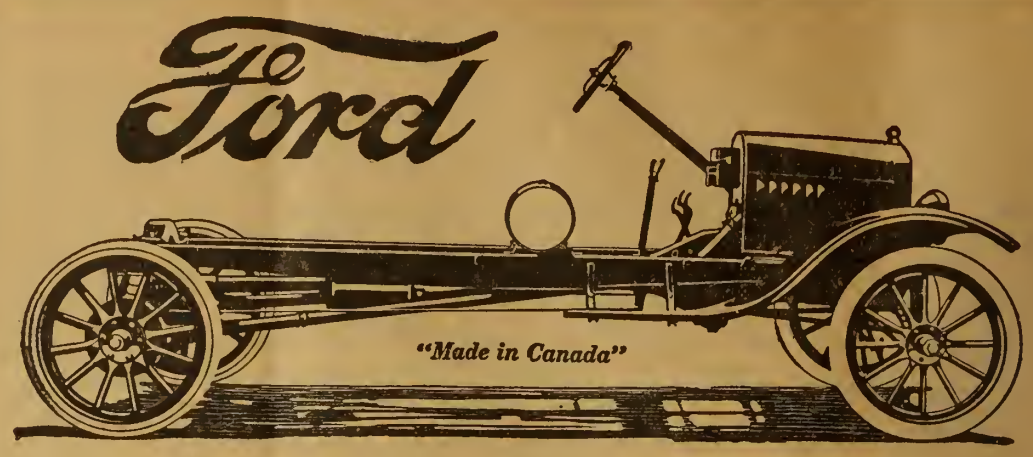
It is announced that Meadowood Pony Farm, Strathmore, near Montreal, has been merged with Mr. T. B. Macaulay's well known Mount Victoria Stock Farm at Hudson Heights, also near Montreal.

Mr. J. E. Chandler, the propietor of Meadowood Farm will be manager of the new pony farm, which without a doubt is the strongest herdo f Shetlands in America. Easily the best blooded Shetlands are in this herd which is headed by the International Champion Silver Star of Transy, which was imported by Mr. Macaulay along with many other famous Shetland ponies from the Shetland Islands.

Mount Victoria Farm is in a position to supply foundation breeding stock, show ponies, young stock and ponies for children and general use.

The bringing together of the two herds means much in the breeding of ponies in Canada. A new pony with all the lovable disposition of the Shetland and the attractive steppin of the Hackey will be produced on the farm by crossing registered prize winning hackey stallions with prize winning Shetland mares.

This is calculated to produce a pony of about twelve hands high suitable for saddle or harness. The Sehtlands will beraised exclusively for children's use and each will be guaranteed.



A Truck for the Farmer

FARM equipment which will effect a time and labor-saving, and therefore a money-saving, must be carefully considered by every good farmer now-a-days.

The farm wagon, which for years was the most useful of all farm equipment, is now being replaced on the best farms by a sturdy, dependable motor truck. The truck will haul any farm product—fruit, grain, vegetables, stock, fertilizer, or wood—around the farm, or to the town or city many miles distant, in half the time, and at a much lower cost.

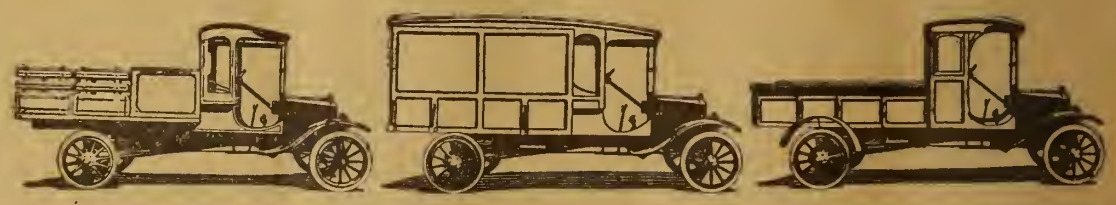
The Ford One-Ton truck is a rapid, economical and very serviceable means of transport. One of these on your farm will save you weeks of time in a single season and will enable you to pass through a crisis of labor shortage with less difficulty.

The Ford truck is supplied as a chassis only. This permits you to select any of the many body styles especially designed for the Ford truck and already on the market. Thus you can mount the one which suits your individual requirements.

Price $750 f.o.b. Ford, Ont.

See any Ford Dealer in Canada, or write for a catalog

Ford Motor Company of Canada, Limited
Ford, Ontario



Three of the many body styles that may be mounted on the Ford truck chassis

ADVANTAGES OF MILK AS A FOOD

To sum up, milk has peculiar advantages as human food:—

1. It contains all classes of food substances, proteins carbohydrates, fats, minerals and vitamines.
2. Its proteins are the most efficient known.
3. Its mineral matter is abundant and well balanced to meet the needs of the young or adults.
4. It contains both water soluble and fat soluble vitamines in comparatively large amounts.
5. Its use controls intestinal bacterial growths and prevents auto-intoxication.
6. It furnishes protein more cheaply than do other foods which are as easily and cheaply digested, such as meat and eggs.
7. It is recognized as absolutely necessary for the growth and health of children.

Horses feed naturally on the ground. Remember this in arranging the mangers and feed boxes.

Adjust the hames to the collar and save sore necks and shoulders.

Lawndale Stock Farm
Jerseys and Shorthorns (Pure Bred)

JERSEYS

Two registered heifers, dropped in May, 1918; solid color (fawn.) The dams of these calves are heavy milkers; the sires are our two herd bulls.

bulls, also two registered bull calves dropped in August, 1918.

We have just received three females imported direct from the Island of Jersey.

SHORTHORN:—

One yearling heifer, just bred, red, and a heifer calf, dropped in June, 1918, red, little white. The dams are good milkers, the sire a son of "Stately Monarch," grand champion in three Provincial Shows. Our Shorthorn herd bull was recently imported from the herd of Lord Rothschild, Tring Park, England.

I. M. LOVITT, M.D.,
Yarmouth North, - Nova Scotia

Maple Green Farm Holsteins

Just now we are offering some fresh calved cows and some due to freshen shortly, also yearling heifers and heifer calves, all with official records or from official record dams. Remember this is the only herd in Eastern Canada which owns two Jr. 3 year olds with official records of 25.05 and 26.54 lbs. butter in 7 days.

Herd sires in service. "Maple Grove Mercena Mercedes," No. 11727, the sire of our 26.54 lb. Jr. 3 year old and who so far has not a tested daughter testing under 4%. Our Jr. herd sire, "Homestead Hengerweld Rooker," No. 20652, three-quarter brother to our 25.05 lb. Jr. 3 year old.

For particulars write

OINTMENTS AND SPRAYS TO KEEP THE FLIES AWAY FROM CATTLE

There is nothing that will keep flies entirely away from cattle but any one of the following mixtures wlil be found useful:

1 pound rancid lard; ½ pint kerosene. (Apply with the hands or brush.)

3 parts fish oil; 1 part kerosene. (Apply with small spray pump.)

2 parts cottonseed oil, or fish oil; 1 part pine tar. (Apply with large paint brush.)

2 ounces pennyroyal; 1 quart of olive or rape oil. (Apply with brush.)

In case of the horn fly, pine tar or crude oil may be plastered around the base of the horn or used somewhat diluted over the head and shoulders.—Geo. H. Glover, Colorado Agricultural College, Fort Collins, Colo.
